# Important physical and mathematical basics

## 1 Common SI prefixes

Prefix	Abbreviation	Meaning
Femto	f	10 <sup>-15</sup>
Pico	p	$10^{-12}$
Nano	n	$10^{-9}$
Micro	μ	$10^{-6}$
Milli	m	$10^{-3}$
Centi	c	$10^{-2}$
Deci	d	$10^{-1}$
Kilo	k	10 <sup>3</sup>
Mega	М	$10^{6}$
Giga	G	109
Tera	Т	10 12

## 3 Perimeters, areas and volumes of some geometric shapes

#### A. Plane geometric shapes:

Figure	Square	Rectangle	Triangle	Circle
Geometrical shape			1, 1,	(1)
Perimeter	41	$2(l_1 + l_2)$	$l_1 + l_2 + l_3$	2 πr
Area (A)	12	$\ell_1 \times \ell_2$	$\frac{1}{2} l_1 \times h$	$\pi r^2$

#### B. Solid geometric shapes:

Figure	Cube	Cuboid	Sphere	Cylinder
Geometrical shape				
Volume (V)	<i>l</i> <sup>3</sup>	$l_1 \times l_2 \times l_3$	$\frac{4}{3}\pi r^3$	$\pi r^2 \times h$

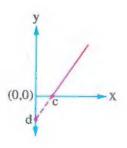

## 4 Graphical representations of some relations between two variables

Relation	Graph	
$y = mx$ - At x = zero $\implies$ y = zero $* \text{ The straight line passes by the origin } (0,0)$ $Slope = \frac{\Delta y}{\Delta x} = m \text{ (Direct relation)}$	(0,0) X	
$y = a + mx$ - At x = zero $\Rightarrow$ y = a (positive value) * The straight line intersects y-axis at point (a) At y = zero, x = b (negative value) = $-\frac{a}{m}$ $Slope = \frac{\Delta y}{\Delta x} = m$	b (0,0) X	

$$y = mx - d$$

- y = mx d- At  $y = zero \implies x = \frac{d}{m} = c$  (positive value)
- \* The straight line intersects x-axis at point (c).
- At  $x = zero \implies y = -d$  (negative value)

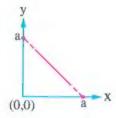

Slope = 
$$\frac{\Delta y}{\Delta x}$$
 = m

$$y = a - x$$

- The sum of the two quantities x, y at any point = constant value (a)
- At  $x = zero \implies y = a$  (constant value)
- At  $y = zero \implies x = a$  (constant value)

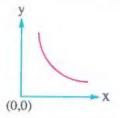

Slope = 
$$\frac{\Delta y}{\Delta x} = -1$$

$$y = \frac{a}{x}$$

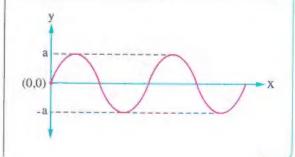

- The product of two quantities x, y at any point equals constant value (a).

(Inverse relation)

$$y = a \sin(x)$$

- The value of (y) varies between (a, -a)with the change of x.

## The used physical quantities, their symbols and units of measurement

Physical quantity	Symbol	Unit of measurement	
Displacement or distance	d T	meter	m
Amplitude	A	meter	m
Wavelength	λ (lamda)	meter	m
Frequency	v (Neo)	hertz = second <sup>-1</sup>	$Hz = s^{-1}$
Time	t	second	S
Periodic time	Т	second	S
Wave velocity	v	meter/second	m/s
Refractive index	n	Dimensionless quar	ntity
Speed of light in space	С	meter/second	m/s
Angle of incidence or reflection	ф	degree	deg
Angle of refraction	θ	degree	deg
Critical angle	Фс	degree	deg
The apex angle of a prism	A	degree	deg
Angle of deviation	α	degree	deg
Minimum angle of deviation	ox,	degree	deg
Dispersive power of the prism	ωα	Dimensionless quantity	
Mass	m	kilogram	kg
Volume	V <sub>ol</sub>	meter <sup>3</sup>	$m^3$
Density	ρ	kilogram/meter <sup>3</sup>	kg/m <sup>3</sup>
Force	F	Newton = kilogram.meter/second <sup>2</sup>	N = kg.m/s
Area	A	meter <sup>2</sup>	m <sup>2</sup>
Free fall acceleration	g	meter/second <sup>2</sup>	m/s <sup>2</sup>
Viscosity coefficient	$\eta_{vs}$	Newton.second/meter <sup>2</sup> = kilogram/meter.second	N.s/m <sup>2</sup> kg/m.s
Mass flow rate	Q <sub>m</sub>	kilogram/second	kg/s
Volume flow rate	Q <sub>v</sub>	meter <sup>3</sup> /second	m <sup>3</sup> /s

§ 2 ► Wave Motion.

▶ Test on Chapter 1.

### Chapter objectives

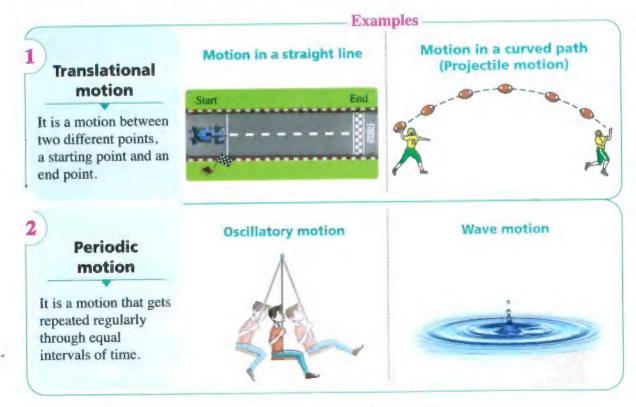

#### By the end of this Chapter, the student should be able to:

- Recognize the meaning of wave motion.
- Recognize the concept of complete oscillation, amplitude, frequency and periodic time.
- · Mention the types of waves.
- Identify the conditions for obtaining mechanical waves.
- Carry out experiments to represent the nature of transverse waves and longitudinal waves.

- Compare between transverse and longitudinal waves.
- Deduce the relation between speed of propagation, frequency and wavelength of a wave.
- Compare between mechanical and electromagnetic waves.
- Acquire the skills to solve problems using the mathematical relations in this chapter.

You have studied that motion can be classified into two types:

 In this chapter, we will study the wave motion, but first, we need to explore some important concepts through studying the oscillatory motion.

# Oscillatory motion

 If a body moves periodically on both sides of a fixed point, whether its motion is in a straight line or in a curved path, this motion is called an oscillatory motion such as the oscillation of:

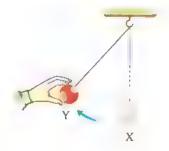

#### The oscillatory motion : -

It is the motion of a vibrating body about its rest position or its equilibrium position that gets repeated through equal intervals of time.

 In the following, we will study the oscillatory motion through studying the motion of a simple pendulum:

When a bob (suspended weight) of a pendulum is displaced sideways its resting position (point X) towards point Y, it will be subjected to a restoring force due to gravity, therefore when releasing the pendulum, it vibrates back and forth on both sides of its equilibrium position and repeats its motion in regular time intervals.

 To study oscillatory and wave motions, we need to explore some initial terms and concepts related to oscillatory motion, these physical concepts can be explained using a simple pendulum as follows:

#### Amplitude (A)

2

When a pendulum is oscillating, its bob moves sideways its rest position (point X) towards any point in its path of motion such as point O or Q where the distance between this point and the equilibrium position is called displacement (d).

Displacement (d)

When the weight of the pendulum is displaced from point X to point Y or Z and left to oscillate, so it moves between the two points (Y, Z) where the maximum displacements of the pendulum away from its equilibrium position are equal in both sides (XY = XZ) and is called the amplitude (A).

i.e

The displacement of a vibrating body:

It is the distance travelled by an oscillating body from its rest or equilibrium position at any moment.

- It is a vector quantity.
- Its measuring unit is meter (m).

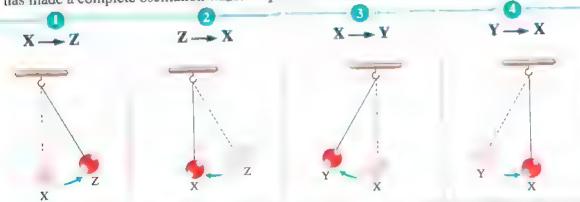

#### The amplitude (A):

It is the maximum displacement of an oscillating body away from its rest or equilibrium position.

- It is a scalar quantity.
- Its measuring unit is meter (m).

### Complete oscillation

 When observing the motion of the pendulum bob starting from point X in a certain direction until it returns back to the same point again moving in the same direction, so the pendulum has made a complete oscillation where its path of motion can be represented as follows:

Hence, we can notice that the pendulum bob passes by point X two successive times in the same direction with the same velocity, *i.e.* the body has the same phase.

▶ If the motion of the body has been observed starting from:

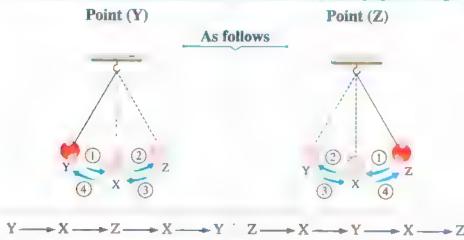

#### Enrichment information

The phase: It is the state of position, velocity and direction of the motion of the body at a certain instant.

Point (Y)

Point (Z)

It makes one complete oscillation at the instant of passing again through

Thus, the complete vibration (oscillation) can be defined as:

#### Complete oscillation:

It is the motion of an oscillating body during a period of time when it passes through a certain point in its path of motion two successive times in the same direction.

The periodic time (T)

The frequency (v)

#### The definition

The time taken by a vibrating body to pass by the same point two successive times in the same direction (to make a complete oscillation).

The number of complete oscillations made by a vibrating body during one second.

The mathematical relation

$$T = \frac{t \text{ (Total time in seconds)}}{N \text{ (Number of complete oscillations)}}$$
$$= 4 \times \text{The time of an amplitude}$$

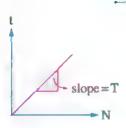

$$\upsilon = \frac{N \text{ (Number of complete oscillations)}}{t \text{ (Total time in seconds)}}$$

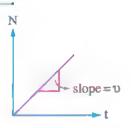

$$= \frac{1}{4 \times \text{The time of an amplitude}}$$

#### The measuring unit

Second (s) which is equivalent to Hertz<sup>-1</sup> (Hz<sup>-1</sup>) Hertz (Hz) which is equivalent to second<sup>-1</sup> (s<sup>-1</sup>)

#### The graph of N versus t

The relation between frequency (v) and periodic time (T)

$$T = \frac{t}{N}$$

$$v v = \frac{N}{t}$$

$$T = \frac{1}{\upsilon}$$

$$\int v = \frac{1}{T}$$

i.e

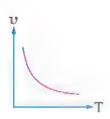

Frequency = The reciprocal of the periodic time, so frequency is inversely proportional to periodic time.

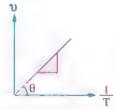

• From the previous, we can represent the graphs of:

Frequency versus periodic time (v-T)

Frequency versus the reciprocal of the periodic time  $(\upsilon - \frac{1}{T})$ 

as follows

Slope = 
$$\frac{\Delta v}{\Delta (\frac{1}{T})} = 1$$

Notice that: The angle  $(\theta) = 45^{\circ}$  only if the two coordinates are drawn with the same scale

# Notes:

- (1) The motion of the pendulum bob from point X to point Z represents a quarter of a complete oscillation.
- (2) The time taken by the bob of the pendulum to move from point X to point Z equals  $\frac{1}{4}$  the periodic time.
- (3) The displacement of the pendulum bob from point X to point Z equals the amplitude.

#### **Enrichment information**

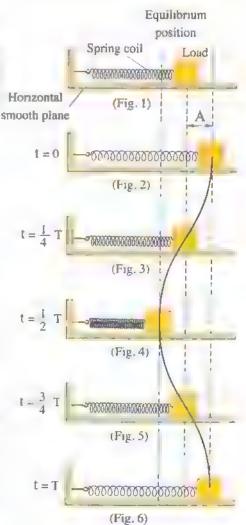

In the ideal simple pendulum, the periodic time (T) depends only on the length ( $\ell$ ) of the thread when the acceleration due to gravity (g) is constant, where:  $T = 2\pi \sqrt{\frac{\ell}{g}}$ 

## Bimplio hannonit mation (CHM)

- Simple harmonic motion is a type of periodic motion such as the motion of a simple pendulum or a body fixed to a spring coil which can be represented by a sinusoidal curve (sine wave) as follows:
- To clarify the simple harmonic motion, we carry out the following experiment:
- one end of a spring to the load and the other end to the wall (fig. 1).
- At pulling the load to the right, the spring gets displaced a distance A and gets elongated (fig. 2).
- When you release the load, the spring exerts a force on the load, pulling it towards the equilibrium position (fig. 3).
- When the load reaches the equilibrium position, its velocity becomes a maximum value and the load exceeds the equilibrium position and completes its motion, hence the spring is compressed and the velocity of the load decreases till it reaches zero when the load reaches a displacement (A) equal to its initial displacement (A) in step 2 (fig. 4).
- When the spring is compressed, the force resulted from the compression of coil turns causes the load to return again to the equilibrium position at which its velocity becomes a maximum value (fig. 5), then the load passes the equilibrium position to make a displacement A for another time (fig. 6).

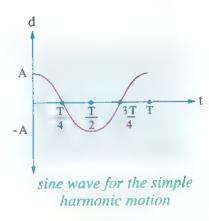

#### **Grandhavenint bylastication**

In simple harmonic motion, there is a force affecting the body (restoring force) whose magnitude increases as the distance between the vibrating body and its initial position of equilibrium increases and it has a direction that is always toward the initial position of equilibrium.

# LINO 1

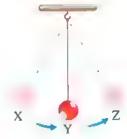

• This motion gets repeated in equal intervals of time, so the relation between the displacement of the load (d) from the equilibrium position and the time (t) can be represented by a sine wave function as shown in the opposite graph:

#### Example 1

In the opposite figure: If the time taken by the pendulum to move from X to Z is 0.8 s, calculate:

- (a) The periodic time.
- (b) The frequency.
- (c) The number of complete oscillations through 16 s.
- (d) The time required to make 50 oscillations.

#### Solution

(a)

When the bob of the pendulum moves from X to Z, it covers half a complete oscillation.

$$T = \frac{t}{N} = \frac{0.8}{\frac{1}{2}} = 1.6 \text{ s}$$

(b) 
$$v = \frac{1}{T} = \frac{1}{1.6} = 0.625 \text{ Hz}$$

(c) 
$$N = \frac{t}{T} = \frac{16}{1.6} = 10$$
 oscillations

Another Solution:  $N = v t = 0.625 \times 16 = 10$  oscillations

(d) 
$$t = NT = 50 \times 1.6 = 80 \text{ s}$$

Another Solution: 
$$t = \frac{N}{v} = \frac{50}{0.625} = 80 \text{ s}$$

#### Example 2

The opposite graph represents the relation between the number of complete oscillations (N) and the time (t), then the frequency of motion of this body equals ......

(a) 0.2 Hz (b) 2 Hz (c) 5 Hz (d) 40 Hz

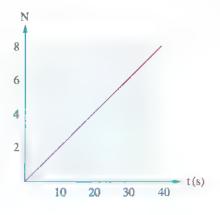

#### Solution

Slope = 
$$\frac{\Delta N}{\Delta t} = \frac{8 - 0}{40 - 0} = 0.2 \text{ s}^{-1}$$

$$v = \frac{N}{t}$$

 $\therefore v = Slope = 0.2 Hz$ 

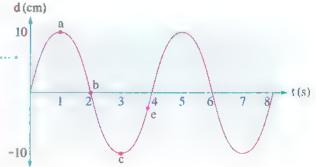

... The correct choice is (a).

#### Example 3

The opposite graph represents the relation between the displacement (d) of an oscillating body and the time (t), then .......

The amplitude		The number of complete oscillations per minute
(a)	10 cm	15
<b>b</b>	20 cm	15
©	10 cm	20
<b>a</b>	20 cm	20

#### Solution

$$t = 1$$
 minute  $A = ?$   $N = ?$ 

$$\Delta = 2$$

$$N = 2$$

- : The amplitude is the maximum displacement of an oscillating body away from its rest position.
- ... From the graph:

A = 10 cm

$$T = 4 s$$

$$T = \frac{t}{N}$$

Through a minute:

$$N = \frac{t}{T} = \frac{1 \times 60}{4} = 15$$

... The correct choice is (a).

What you are asked to determine at which of the four points a, b, c or e,

the object's velocity is greater? What is your answer?

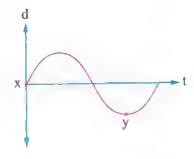

#### Example 4

(b) 
$$8 \times 10^{-3}$$
 s

$$(c)$$
 12.5 × 10<sup>-3</sup> s

(d) 
$$25 \times 10^{-3}$$
 s

#### Solution

$$v = 60 \text{ Hz}$$
  $t_{xy} = ?$ 

#### **Q** Clue

The motion of the mass between the two points x, y represents  $\frac{3}{4}$  complete oscillation and hence the time interval taken by the mass to move between them equals  $\frac{3}{4}$  T.

$$T = \frac{1}{v} = \frac{1}{60} s$$

$$t_{xy} = \frac{3}{4} T = \frac{3}{4} \times \frac{1}{60} = 12.5 \times 10^{-3} s$$

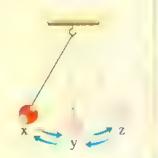

.. The correct choice is ©.

what you have known that the amplitude of the spring is 2 cm, what is the magnitude of the average velocity of the mass when it vibrates between the two points x, y?

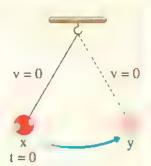

# Test yourself

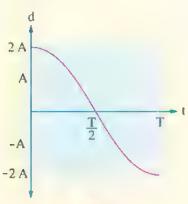

#### 1 Choose the correct answer:

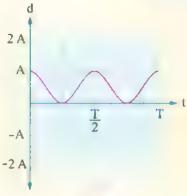

- - (a) the time of motion from x to z
  - (b) the time of motion from y to z
  - © double the time of motion from z to y
  - double the time of motion from z to x

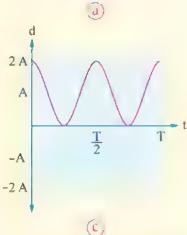

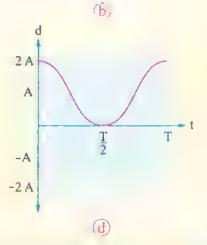

(2) A simple pendulum vibrates with a periodic time T and amplitude A. If the pendulum starts swinging from point x in the direction of point y as shown in the opposite figure, then the graph that represents the relationship between the distance (d) of the bob of the pendulum away from point y and the time (t) is ..........

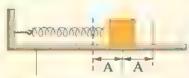

The opposite figure represents a body tied to a spring that makes a simple harmonic motion such that the amplitude of its vibration is A, determine its total displacement and the total distance covered by the body when the body makes a complete oscillation.

A smooth horizontal surface

#### Energy transformations during the motion of simple pendulum

\* Before studying the energy transformations in a simple pendulum, let us remember the concepts of kinetic energy, potential energy and mechanical energy:

Kinetic energy  $KE = \frac{1}{2} \text{ mv}^2$ 

The energy possessed by the body due to its motion

The concept -

A running man

Potential energy
PE = mgh

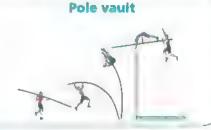

The energy stored in the body due to its state or position

Elongation and compression of a spring

Mechanical energy

E = PE + KE

The summation of the potential energy and the kinetic energy of the body

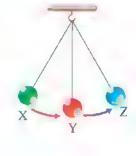

In the following, we will discuss the transformations of energy in a simple pendulum so that when the pendulum bob shown in the opposite figure moves starting from position X, hence:

#### At position X

The pendulum bob has the maximum height relative to its equilibrium position.

#### During its motion from position X to Y

- The vertical height of the pendulum bob decreases gradually, hence its potential energy decreases.
- 1ts kinetic energy increases as its velocity increases.
  - i.e. The potential energy gets converted gradually into kinetic energy since the mechanical energy is constant at all positions.

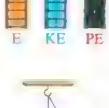

#### — At position Y (The equilibrium position)

- The potential energy of the bob has been completely converted into kinetic energy.
- The velocity of the bob at this position has a maximum value.

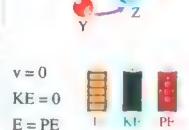

#### During the motion from position Y to Z

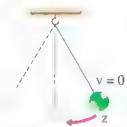

- The height of the pendulum bob increases gradually from its equilibrium position, hence its potential energy increases.
- The velocity of the pendulum decreases gradually as its kinetic energy decreases, hence the kinetic energy gets converted gradually into potential energy since the mechanical energy is constant at all positions.

### At position Z

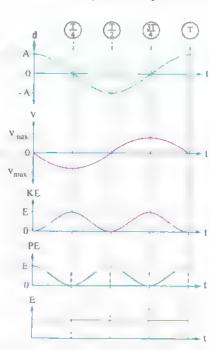

- The kinetic energy gets converted completely into potential energy.
- In the opposite figure, when the pendulum moves starting from point Z, the following graphs represent the variations of some physical quantities related to the motion of this pendulum as time (t) passes through one complete oscillation:

Equilibrium position

- The displacement (d) away from the equilibrium position versus time (t).
- The velocity (v) versus time (t).
- The kinetic energy (KE) versus time (t).
- The potential energy (PE) versus time (t).
- The mechanical energy (E) versus time (t).

# Note:

- In the opposite pendulum when the pendulum bob is displaced from point Y to X then left to vibrate;
- (1) The velocity of the pendulum at point Y is a maximum value.
- (2) The velocity of the pendulum at each of the two points X and Z vanishes.

Hence, we can define the amplitude as follows:

The amplitude:

It is the distance between two successive points in the path of motion of an oscillating body whose velocity becomes a maximum value at one of them and zero at the other.

## Example 1

The opposite figure represents an oscillating tuning fork, so the speed of the fork's arm increases then decreases when it moves from .........

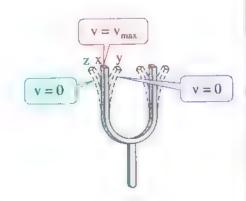

(b) x to y

© y to z

(d) x to z then to x

The opposite figure shows the magnitudes of the speed of the fork's arm at the positions x, y and z, it is noticed that the speed of the fork's arm increases then decreases when it moves from position y to position z or vice versa.

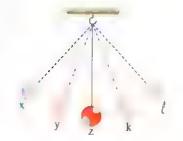

.. The correct choice is ©.

you are asked to determine at which position x, y or z, the mechanical energy of the tuning fork is the greater? What is your answer?

### Example 2

- (a) equal to 8 t
- (b) less than 8 t
- greater than 8 t
- 1 indeterminable

#### Solution

The pendulum moves from x to z with positive acceleration where its velocity increases as it goes down due to the change of its potential energy into kinetic energy, where its average velocity through the displacement vz is greater than through the displacement xy, so the displacement yz takes time less than i and the same for displacement zk, so the time taken to cover the distance xy is greater than half the time of the amplitude i.e. it is greater than  $\frac{1}{8}$  the time of complete oscillation.

- ... The periodic time for the pendulum is less than 8 t.
- .. The correct choice is (b).

# Test yourself

Choose the correct answer:

- The opposite figure shows the motion of a simple pendulum. If xy = yz = zk = kl, so
  - (a) the kinetic energy at k > The potential energy at x
  - b the potential energy at  $\ell$  < The potential energy at y
  - (c) the kinetic energy at y = The kinetic energy at k
  - the kinetic energy equals the potential energy at all points

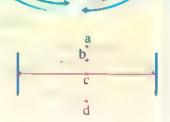

$$\bigcirc$$
  $\frac{(PE)_a}{(PE)_d}$ 

$$\bigcirc \frac{(PE)_b}{(PE)_d}$$

## **Oscillatory Motion**

The questions signed by 🌟 are answered in detail

- 1) The motion of a body in a circular path with a constant speed is considered . .
  - a a periodic motion

(b) a simple harmonic motion

· rule ca

(c) an oscillatory motion

- d a wave motion
- The motion of a swing is considered ...........
  - (a) a translational motion

(b) a wave motion

(c) an oscillatory motion

- d a circular motion
- In the opposite figure, the pendulum makes a complete oscillation when it moves from ...

 $(\mathbf{d}) \times \longrightarrow \mathbf{y} \longrightarrow \mathbf{z} \longrightarrow \mathbf{y} \longrightarrow \mathbf{x}$ 

\* In the opposite figure, a body moves in an oscillatory motion, so the distance which is moved by the body during a complete oscillation equals ......

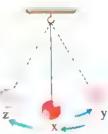

a double the distance AB

b, double the distance BC

c half the distance AC

- d four times the distance BC
- 5 The opposite figure shows a simple pendulum vibrating with an amplitude A. If its bob has moved from position x to position y then to position z, the magnitude of displacement of the pendulum bob equals .

- A simple pendulum started a simple harmonic motion from the farthest position away from its equilibrium position at t = 0. If the periodic time of the pendulum is T, then which of the following graphs represents the relation between the kinetic energy (KE) of the pendulum bob and the time (t)?

#### Answer the following questions:

A body suspended by a string is pushed to the right to swing left and right about its original equilibrium position, the opposite graph represents the relation between the displacement (d) starting from the moment of pushing the body and time (t) through 8 s, if we consider that the direction of its motion to the right is the positive direction, then at which moment or moments during this period the body will be:

- (a) moving towards the right with a maximum speed?
- (b) moving towards the left with a maximum speed?
- (c) static instantaneously?

What happens when a stone is dropped in a still lake

#### 2 When a stone is dropped into water, as in the figure ::

Water waves

- The collision of the stone with water becomes a source of disturbance.
- This disturbance propagates on the surface of water in the shape of uniform concentric circles, whose center is the position at which the stone falls.
- These circles transfer energy in the same direction of their propagation.
- These circles are called water waves and their propagation represents a wave motion.
- Erom the previous, we can define the wave as follows:

#### The wave:

It is a disturbance that propagates and transfers energy in the direction of propagation.

• When a wave propagates in a medium, the particles of the medium vibrate about their equilibrium positions without moving away from their equilibrium positions, this becomes clear when placing a piece of cork on the surface of water and causing a disturbance in the water, we find that the piece of cork moves up and down without moving from its position as in the following figures but the waves propagate in the water and thus energy is transmitted.

Direction of wave propagation

Cork

Figure (1)

Figure (2)

Figure (3)

## Types of waves

- Many forms of waves exist around us, some waves can be seen such as water waves, other waves cannot be seen but we can detect them such as radio and X-ray waves.
- Waves can be classified into:

First

Mechanical waves

Second

Electromagnetic waves

#### (First Moth

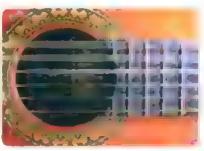

- Mechanical waves are produced due to the vibration of a body in a medium, so the vibration (disturbance) propagates from the body through the medium.
- Propagation: They need a medium through which they can propagate.
- ► Examples:

Water waves

Sound waves

Waves that propagate in strings during their vibrations

#### Conditions of obtaining mechanical waves

#### The existence of a vibrating source:

- Like: A vibrating string
  - The vibrating arms of a tuning fork.
- The occurrence of a disturbance that transfers from the source to the medium:
  Like the formed disturbances when the arms of a tuning fork gets vibrating.

#### The existence of a medium to transmit the disturbance:

Mechanical waves (like sound waves) need a medium through which they can travel because the particles of the medium vibrate about their equilibrium positions without moving away from their positions to transfer the mechanical energy of the wave, so they can not propagate in space.

## Note:

- Since sound is a mechanical wave, it cannot propagate in empty space, so:
- The sounds of cosmic explosions that happen in the outer space cannot be heard.
- Astronauts use wireless devices to communicate in space.

#### Types of mechanical waves

0

**Transverse waves** 

**2**Longitudinal waves

Transverse waves

To describe the nature of transverse waves, we carry out the following experiment:

# Experiment

#### teps and observations:

- 1. Bring a long rope and fix its end to a vertical wall.
- 2. Hold the other end of the rope with your hand.
- Move the end of the rope with your hand up and return it to the original position once.

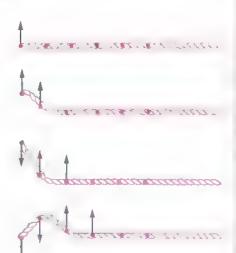

Observation: A pulse wave is generated through the rope,

A pulse:

It is a single disturbance in the form of a half wave.

#### **Explanation:**

- Energy gets transferred from the source to its adjacent part in the rope, hence this part moves upward.
- The tension force in the rope brings this part downwards, hence the energy gets transferred to next adjacent part, so this part moves upward and so on.
- The parts of the rope vibrate up and down successively.

 Continue in moving the end of the rope up and down with a constant rate.

**Observation:** The end of the rope moves upwards and downwards in a simple harmonic motion that transfers along the rope as continuous wave pulses (transverse wave train) (figure (2)).

### Conclusion:

- (1) The direction of propagation of the wave through the rope is:
  - The direction of energy propagation.
  - Perpendicular to the direction of motion (vibration) of the medium particles (the rope) about their equilibrium positions.

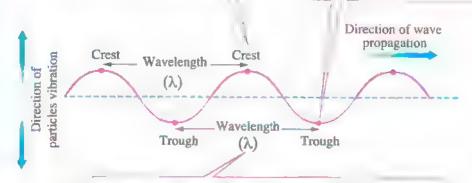

### A transverse wave:

It is a wave in which the directions of medium particles vibrations about their equilibrium positions are perpendicular to the direction of wave propagation.

(2) The transverse wave consists of crests and troughs as shown in the following figure:

The position that represents the maximum displacement of the medium particles in the positive direction (positive pulse)

The position that represents the maximum displacement of the medium particles in the negative direction (negative pulse).

The distance between two successive crests or two successive troughs or any two successive points along the direction of propagation that are in the same phase is called the wavelength of the transverse wave (4)

### Notice that:

A medium particle has the same phase at a definite position, when it passes through that position two successive times with the same velocity (including magnitude and direction).

### **Examples of transverse waves:**

Battle rope waves

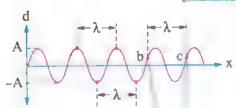

Water surface waves

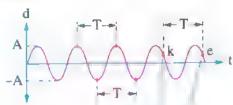

### Graphical representation of transverse waves

- The motion of the particles of the medium in which the transverse wave propagates can be represented through the graphs of :
  - 1 The displacement of the particles of the medium (d) versus the horizontal distance (x) covered by the wave at a certain instant.
- The displacement of one of the medium particles (d) versus time (t).

The two points b,c have the same phase

The two points e,k
have the same phase

From the two graphs, we find

$$\lambda = \frac{x \text{ (Total distance)}}{N \text{ (Number of waves)}}$$

$$v = \frac{N \text{ (Number of waves)}}{t \text{ (Time in seconds)}} = \frac{1}{T}$$

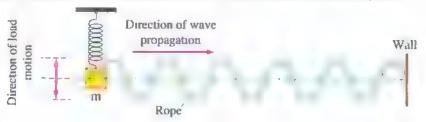

• From the previous, we can define the wave amplitude (A) as follows:

### The wave amplitude (A):

It is the maximum displacement of the vibrating medium particles away from their equilibrium positions.

### Notes:

(1) Transverse waves can be obtained by using a load held to a vertical spring that can vibrate up and down about its equilibrium position. The load is attached to a horizontal rope whose other end is fixed to a vertical wall, as the following figure:

In such case, the frequency of the transverse wave that propagates in the rope equals the frequency of the oscillatory motion of the load that is suspended to the spring.

- 12) The amplitude of a transverse wave propagating in a stretched string depends on the work done by the vibrating source (the hand or a vibrating load) and that work gets transferred through the particles of the string in the form of:
  - Potential energy as a tension in the rope.
  - Kinetic energy as a vibration in the rope.
- ... The amplitude of the wave doesn't depend on any of the frequency or the wavelength of the wave.

### **Enrichment Information**

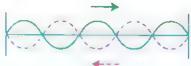

Travelling waves and standing waves can be distinguished from each other as follows:

### Travelling wave

The wave that propagates in one direction continuously moving away from its source.

The wave that results from the overlap of waves that get reflected repetitively between two points.

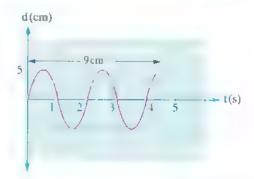

A standing wave on a string stretched between two clamps

### Example 1

The opposite graph represents a transverse wave, calculate:

- (a) The amplitude.
- (b) The frequency.
- (c) The periodic time.
- (d) The wavelength.

### Solution

$$(a) A = 5 cm$$

**(b)** 
$$v = \frac{N}{t} = \frac{2.25}{4.5} = 0.5 \text{ Hz}$$

$$(c) T = 2 s$$

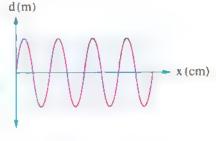

(d) 
$$\lambda = \frac{x}{N} = \frac{9}{2.25} = 4 \text{ cm}$$

you are asked to determine the time interval between the passing of the second crest and the tenth crest by a definite point in the direction of wave propagation, what is your answer?

### Example 2

The opposite graph represents the relation between the displacement (d) of the medium particles in which a transverse wave is travelling at a certain instant and the distance (x) travelled by the wave, if the distance between the first trough and the seventh crest is 5.5 cm, the wavelength of the wave equals ....

(a) 5.5 cm

(b) 5 cm

(c) 1 cm

(a 0.5 cm

### Solution

$$x = 5.5 \text{ cm}$$
  $\lambda = ?$ 

The number of waves between the first trough and the seventh crest:

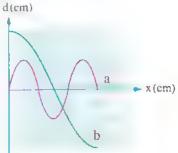

$$N = (7 - 1) - \frac{1}{2} = 5.5$$

$$\lambda = \frac{x}{N} = \frac{5.5}{5.5} = 1 \text{ cm}$$

... The correct choice is (c).

### Example 3

The opposite graph represents the relation between the displacement (d) of the medium particles and the distance (x) travelled by two transverse waves a , b , so the ratio 

 $\frac{3}{1}$  (b)  $\frac{3}{4}$  (c)  $\frac{1}{1}$  (d)  $\frac{1}{3}$ 

### Solution

### Q Clue

From the graph, we find that when the two waves cover the same horizontal distance, wave a makes 1.5 complete waves and wave b, makes 0.5 complete wave.

$$\lambda = \frac{x}{N}$$

$$\therefore \frac{\lambda_a}{\lambda_b} = \frac{N_b}{N_a} = \frac{0.5}{1.5} = \frac{1}{3}$$

 $\therefore$  The correct choice is  $(\mathbf{d})$ .

hai n you are asked to determine the ratio between the amplitudes of the two waves  $\left(\frac{A_a}{A_b}\right)$ , what is your answer?

### Test yourself

- The opposite graph represents a transverse wave, calculate:
  - (a) The periodic time.
  - (b) The frequency.
  - (c) The wavelength.

Choose the correct answer:

The opposite graph represents the relation between the displacement (d) and the time (t) for a transverse wave, then:

- (a) 2 c
- **(b)**  $\frac{1}{2}$  b
- © 2 e
- (d) 2 a

- (a) c
- (b) e
- $\frac{1}{2}$  a
- $\bigcirc \frac{1}{2}$  b
- (iii) Increasing the wavelength to the double leads to ..............
  - (a) increasing distance c to four times its original value
  - b increasing distance a to the double
  - c decreasing distance b to its half
  - d unchanging distance e

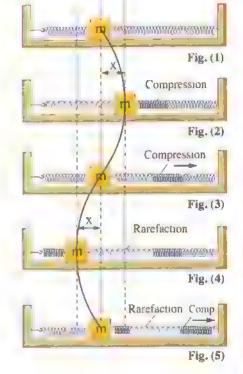

### Longitudinal waves

To describe the nature of longitudinal waves, we carry out the following experiment:

### Experiment

### Steps and observations:

- 1. Put a load (m) on a smooth horizontal plane and attach the load between two springs, one of them is longer than the other and each of them is attached to a wall (figure 1).
- 2. Pull the load to a distance x to the right side.
- 3. A part of the spring which is adjacent to the load gets compressed at the right side forming a pulse of a compression (figure 2).
- 4. Leave the load free, so the load returns to its equilibrium position by the effect of the force generated in the spring at the left of the load, while the pulse of compression travels through the spring to the right of the load (figure 3).
- 5. The load exceeds the equilibrium position, moving to the left, creating a rarefaction in the spring towards the right (figure 4).
- 6. The motion of the load gets repeated to the right and the rarefaction pulse travels to the right (figure 5).

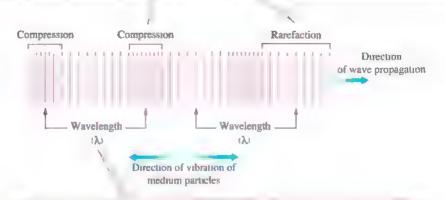

### Conclusion:

(1) During the vibration of the load, a wave propagates in the spring where the direction of vibration of the medium particles is along the same line of the wave propagation, such wave is called longitudinal wave.

(2) The longitudinal wave consists of a group of compressions and rarefactions which transfer along the spring as shown in the following figure:

The region where the particles of the medium become close to each other.

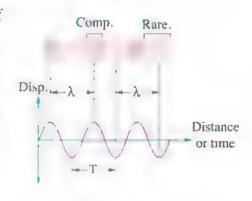

The region where the particles of the medium become far from each other.

- The distance between the centers of two successive compressions, two successive rarefactions or any two successive points along the direction of propagation that are in the same phase is called the wavelength of the longitudinal wave.
- Examples of longitudinal waves: Sound waves in gases. Waves inside water.

### Graphical representation of longitudinal waves

When we plot the relation between the displacement of the medium particles and the distance travelled by the wave at a given instant or between the displacement and the time for the motion of the medium particles in which the longitudinal wave propagates, we get a sine wave curve as shown in the opposite figure, hence all the concepts and the laws of the transverse wave are applicable to this curve.

### Notes:

### H-We can get transverse and longitudinal waves using a long spring coil

A transverse wave or a longitudinal wave can be produced in a long spring coil depending on the direction of the vibration of the wave source (a vibrating body) where the particles of the medium vibrate in the same way as the vibrating source, when fixing a spring coil horizontally from one of its ends while moving the other end of the coil:

# Up and down The formed wave will be Transverse Longitudinal A (2) The pulse can be defined as a single disturbance forming a single half wave such as a single crest, a single trough, a single compression or a single rarefaction. Compression pulse Compression pulse Trough pulse

From the previous, we can compare between the two types of mechanical waves (transverse and longitudinal) as follows:

	Transverse wave	Rarefaction $\lambda$ Compression	
Wave form	Crest \(\lambda\) Trough \(\lambda\)		
Direction of vibration of medium particles	Perpendicular to the direction of wave propagation.	Along the line of wave propagation.	
Wavelength	The distance between two successive crests or two successive troughs.	The distance between the centers of two successive compressions or the centers of two successive rarefactions.	
Examples	<ul><li>Propagating waves in strings.</li><li>Waves on water surface.</li></ul>	Sound waves in gases.     Waves inside water.	

### Enample

The opposite figure represents a longitudinal wave

If the distance between the two points a and b is 1.7 m

and the time taken by the wave to travel from c to d is

0.015 s, calculate:

- (a) The wavelength of the longitudinal wave.
- (b) The frequency of the wave.

### Solution

$$x_{ab} = 1.7 \text{ m}$$
 |  $t_{cd} = 0.015 \text{ s}$  |  $\lambda = ?$  |  $v = ?$ 

(a) 
$$\lambda = \frac{x_{ab}}{N_{ab}} = \frac{1.7}{0.5} = 3.4 \text{ m}$$

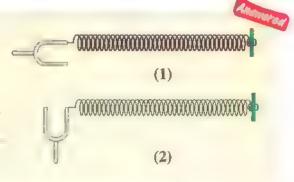

(b) 
$$v = \frac{N_{cd}}{t_{cd}} = \frac{1.5}{0.015} = 100 \text{ Hz}$$

you are asked to calculate the distance between the two points a, d and the time taken by the longitudinal wave to travel between them, what will be your answer?

### Test yourself

The opposite figures show two tuning forks attached to two springs.

What is the type of wave that will be produced in each case when the forks vibrate?

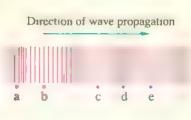

### Choose the correct answer:

**b** 
$$\frac{2}{1}$$

$$\bigcirc \frac{3}{2}$$

$$\frac{3}{1}$$

### Second

### Electromagnetic waves

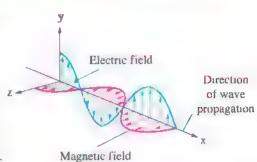

### **Electromagnetic waves:**

They are waves that originate from the vibration of electric and magnetic fields with the same frequency where both fields are in the same phase perpendicular to each other and to the direction of their propagation.

 Propagation: They travel either in physical media or in empty space where their speed in space reaches its maximum constant value that equals 3 × 10<sup>8</sup> m/s.

• Types: Transverse waves only.

From the previous, we can compare between mechanical and electromagnetic waves as follows:

### Mechanical waves **Electromagnetic** waves Waves originated from the vibration Waves originated from the of electric and magnetic fields vibration of medium particles either Concept perpendicular to each other and to perpendicular to the direction of wave propagation or along the line the direction of the wave of the wave propagation. propagation. They don't require a medium They require a medium through to propagate, so they can travel which they can propagate. Propagation through empty space. Transverse and longitudinal waves Transverse waves only **Types** Light waves. Water waves. · Sound waves. Radio waves. Examples Propagating waves in strings. X-ray waves.

### Dedocing the special of propagation of the waters

 If a wave has travelled a distance x through a time interval t, the speed of the wave (v) is calculated from the relation:

 $v = \frac{x}{t}$ 

So, if the distance equals its wavelength  $(\lambda)$ , then the wave takes a time equal to its periodic time (T).

$$\therefore x = \lambda, t = T$$

$$\therefore v = \frac{\lambda}{T}$$

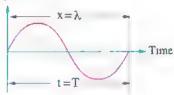

$$\because \upsilon = \frac{1}{T}$$

$$v = \lambda v$$

### Wave speed (v):

It is the distance travelled by the wave in one second in the direction of propagation.

This relation is applicable to all types of waves (mechanical or electromagnetic).

### The factors that affect. The speed of a wave in a medium

- (1) The type of wave (mechanical or electromagnetic).
- (2) Type of the medium material (solid, liquid, gas).
- (3) The physical properties of the medium material (such as the density, elasticity, temperature) and it does not depend on the frequency of the wave, its wavelength or its amplitude.

Where

### Note:

• When applying the relation of  $v = \lambda v$  on:

### Two waves of the same type propagating in the same medium

The speed of the two waves will be the same because the wave speed depends only on the medium type.

$$v_1 = v_2$$

$$\lambda_1 v_1 = \lambda_2 v_2$$

$$\therefore \frac{\lambda_1}{\lambda_2} = \frac{v_2}{v_1}$$

### A wave travelling from one medium to another

The frequency of the wave remains constant because the wave frequency depends on the source frequency.

$$v_1 = v_2$$

$$\frac{\mathbf{v}_1}{\lambda_1} = \frac{\mathbf{v}_2}{\lambda_2}$$

$$\frac{\lambda_1}{\lambda_2} = \frac{v_1}{v_2}$$

 $\lambda_1$  and  $\upsilon_1$  are the wavelength and the frequency of the first wave,  $\lambda_2$  and  $\upsilon_2$  are the wavelength and the frequency of the second wave.

 $\lambda_1$  and  $v_1$  are the wavelength and the speed in the first medium,  $\lambda_2$  and  $v_2$  are the wavelength and the speed in the second medium.

# LINA 1

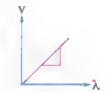

### · i.e. ·

- The wavelength is inversely proportional to the frequency (0) at constant wave speed (v).
- The wavelength is directly proportional to the wave speed (v) at constant frequency (v).

### Graphical representation

Slope = 
$$\frac{\Delta v}{\Delta(\frac{1}{\lambda})} = v$$

Slope = 
$$\frac{\Delta v}{\Delta \lambda} = v$$

### Example 1

Electromagnetic waves propagate in space at a speed  $c = 3 \times 10^8$  m/s. If the wavelength of an electromagnetic wave is 5000 Å, what is the frequency of this wave? (Given that: 1 Angstrom (Å) =  $10^{-10}$  m)

### Solution

$$c = 3 \times 10^8 \text{ m/s}$$
  $\lambda = 5000 \text{ Å}$   $v = 10^8 \text{ m/s}$ 

$$\lambda = 5000 \times 10^{-10} = 5 \times 10^{-7} \,\mathrm{m}$$

$$c = \lambda v$$

$$3 \times 10^8 = 5 \times 10^{-7} \times v$$

$$v = \frac{3 \times 10^8}{5 \times 10^{-7}} = 6 \times 10^{14} \text{ Hz}$$

Winc

you are asked to calculate the average time taken by the light to reach the Earth from the Sun knowing that the average distance between the Sun and the Earth is  $1.5 \times 10^8$  km, what will be your answer?

### Example 2

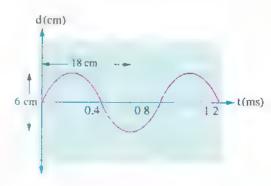

The opposite graph represents the relation between the displacement (d) of one of the particles of a medium and the time (t) for a longitudinal wave propagating in this medium, then the speed of propagation of this wave in the medium equals .....

c) 225 m/s

(d) 300 m/s

### Salution

$$\lambda = \frac{X}{N} = \frac{18}{0.75} = 24 \text{ cm}$$

$$v = \frac{N}{t} = \frac{1.5}{1.2 \times 10^{-3}} = 1250 \text{ Hz}$$

$$v = \lambda v = 24 \times 10^{-2} \times 1250 = 300 \text{ m/s}$$

.. The correct choice is (d).

you are asked to determine whether the ratio between the speed of wave propagation and the average speed of the vibration of one of the medium particles is greater than one, equal to one or less than one? What will be your answer?

### Example 3

A sound wave of wavelength  $\lambda$  propagates in air with a speed of 330 m x, if it has travelled to another medium in which its speed is 990 m/s, then its wavelength increases by .............

a 
$$\lambda$$

### Solution

$$v_1 = 330 \text{ m/s}$$
  $v_2 = 990 \text{ m/s}$   $\lambda_1 = \lambda$   $\Delta \lambda = ?$ 

$$v = v \lambda$$

.. The wave is transferred to another medium.

... The wave frequency (v) is constant.

$$\therefore \frac{\mathbf{v}_1}{\mathbf{v}_2} = \frac{\lambda_1}{\lambda_2}$$

$$\therefore \frac{330}{990} = \frac{\lambda}{\lambda + \Delta\lambda}$$

$$3\lambda = \lambda + \Delta\lambda$$

$$\Delta \lambda = 2 \lambda$$

.. The correct choice is (b).

### Example 4

Two tones, whose frequencies are 340 Hz and 212 Hz, travel in air. If the wavelength of one of them is longer than the other by 60 cm, then the speed of sound in air equals ......

### Solution

$$v_1 = 340 \text{ Hz}$$
  $v_2 = 212 \text{ Hz}$   $\Delta \lambda = 60 \text{ cm}$   $v = ?$ 

### Q Clue

When two waves have the same speed, the longer wavelength belongs to the smaller frequency.

$$\lambda_{2} = \lambda_{1} + \Delta \lambda = \lambda_{1} + 0.6$$

$$\frac{\upsilon_{1}}{\upsilon_{2}} = \frac{\lambda_{2}}{\lambda_{1}} , \frac{340}{212} = \frac{\lambda_{1} + 0.6}{\lambda_{1}}$$

$$340 \lambda_{1} = 212 \lambda_{1} + 127.2 , \lambda_{1} = \frac{159}{160} \text{ m}$$

$$v = \upsilon_{1} \lambda_{1} = \frac{159}{160} \times 340 = 337.9 \text{ m/s}$$

.. The correct choice is (a).

### Example 5

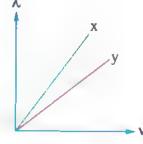

The opposite graph represents the relation between the wavelength  $(\lambda)$  for two waves (x, y) propagating in different media and the speed (v) of these two waves in each of these media, so which of the following relations is correct?

$$(b) v_x > v_y$$

$$\bigcirc T_x > T_y$$

$$\mathbf{d} \mathbf{v}_{x} = \mathbf{v}_{y}$$

### Solution

$$\therefore v = \lambda v$$

$$\therefore v = \lambda v$$

$$\therefore \text{Slope} = \frac{\Delta \lambda}{\Delta v} = \frac{1}{v} = T$$

$$\therefore$$
 (slope)<sub>x</sub> > (slope)<sub>y</sub>

$$\therefore v_{y} > v_{x}, T_{x} > T_{y}$$

you know that one of the two waves (x, y) is a red light wave and the other is a blue light wave, so which of them is the red light wave and which is the blue light wave?

### **Test yourself**

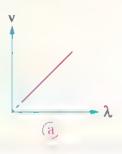

ise the correct answer

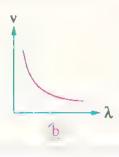

- - $\frac{3}{4}$

Water surface

Load

- Waves transmit .- .... in the direction of their propagation.

(d) water

- a matter
- (b) particles
- 2 \* The opposite figure represents two waves interfering on the surface of water, which two points in the figure represent the sources of these waves?

(b) T. R

(c) Q, T

- (d) U, O
- The opposite figure shows a wave propagating on the surface of a still lake, so this wave propagates in ........
  - (a) one direction with an increasing speed
  - b two opposite directions with two different speeds
  - (c) all directions with the same speed
  - (d) all directions with increasing speed
- A load is suspended to a piece of cork that floats on the surface of the water as shown in the figure, when a wave passes on the surface of water in the direction from x to y, in which direction does the piece of cork move?

- b. Up and down.
- (c) From x to y.
- (d) From y to x.
- A train of waves passes on the water surface of a lake as shown in the opposite figure. What will be the level at which the surface of water settles after the waves finish passing?

(b) B

(c) C

Piece of cork

 $(\mathbf{d}, \mathbf{D})$ 

In the opposite wave, which of the points a, b, c, d have the same phase?

(a a, b, c

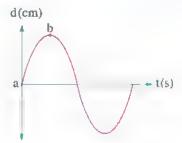

(b) a, b

(c) b, c

(d) b, d

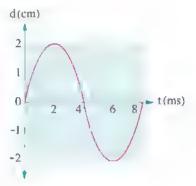

\* The opposite figure represents the relation between the vertical displacement (d) of one of the medium particles and the time (t) for a transverse wave of frequency that equals 50 Hz, then the time interval taken by the medium particle to move between the two points a and b is .............

(a)  $\frac{2}{25}$  s

- $\frac{1}{50}$ s
- (b)  $\frac{1}{25}$ s (d)  $\frac{1}{200}$ s
- The opposite figure represents a transverse wave, so:
  - (i) The amplitude of this wave is
    - (a) 2 cm
- (b) 3 cm
- (c) 4 cm

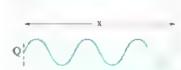

- d, 6 cm
- (ii) The frequency of this wave is ......
- (a) 100 Hz
- (b) 125 Hz
- © 250 Hz
- d 500 Hz

- \* If the time interval between passing the first crest and the tenth crest by a point in the path of a wave motion is 0.2 s, then the frequency is . ......
  - (a) 45 Hz
- (c) 55 Hz
- 10 A girl dropped a stone in water pond and watched the formed waves. She found that 18 waves had collided with the edge during 10 s. If the distance between every two successive crests was 12 cm, so ............

	The wavelength (cm)	The frequency (Hz)
(a)	24	1.8
<b>(b)</b>	24	0.6
0	12	1.8
(d)	12	0.6

1 The opposite two figures represent two water waves P and Q propagating for a distance x with the same speed, which of these two waves has the largest amplitude and which has the highest frequency?

	The wave of the largest amplitude	The wave of the highest frequency
(a)	P	P
<b>b</b>	P	Q
<b>©</b>	Q	P
<b>(d)</b>	Q	Q

- The opposite graph represents the relation between the displacement (d) of the particles of a medium in which a transverse wave propagates with frequency v, amplitude A and the distance (x) travelled by the wave, if:
  - (i) The frequency of the wave is doubled at constant amplitude, then distance .......
  - (a) a increases to the double

b increases to the double

c decreases to its half

- (d) e decreases to its half
- (ii) The amplitude of the wave is doubled at constant frequency, then distance ......
- (a) a decreases to its half

(b) b decreases to its half

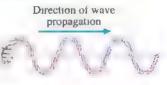

c increases to the double

- d e increases to the double
- \* If the wavelength of a transverse wave is  $\lambda$ , then the distance between the first crest and the crest of order n equals ......
  - (a) n \lambda

- (b)  $(n+1)\lambda$
- $(c)(n-1)\lambda$
- (1)  $(n-\frac{1}{2})\lambda$

In the opposite wave, if the distance between the first crest and the third trough is 100 cm, then the wavelength for this wave equals .....

- (a) 10 cm
- (b) 20 cm
- (c) 40 cm
- (d) 70 cm
- The following figures show four sources of waves, which of them produces longitudinal waves in its surrounding medium?

Light bulb

(a)

Horn speaker

TV remote control

Water surface waves

The opposite figure represents a model of sound wave propagating through air inside a tube opened from both ends, how to describe region Q?

- . A region of high density which is called compression.
- h A region of low density which is called compression.
- . A region of high density which is called rarefaction.
- d) A region of low density which is called rarefaction.
- If the distance between two successive points having the same phase for a wave equals 50 cm, then the wavelength of this wave equals ......

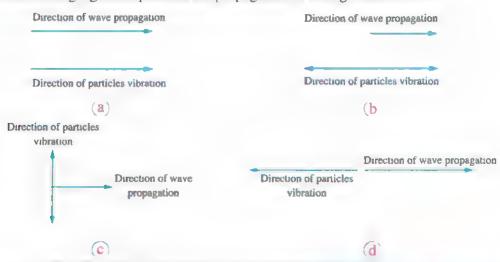

(a) 0.125 m

(b) 0.25 m

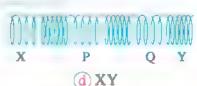

© 0.5 m

(d) 1 m

Which of the following figures represents the propagation of a longitudinal wave?

In the opposite figure, a longitudinal wave propagates in a spring, then the wavelength of this wave is the distance .....

(a)PO

a halved

(b) 2 PO

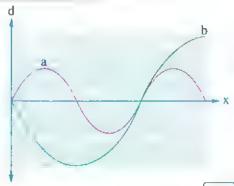

b doubled

 $\bigcirc \frac{XY}{2}$ 

quadrupled

When the frequency of a wave gets doubled, the periodic time of the wave gets . . . . . . . d unchanged

The opposite graph represents the relation between the displacement (d) of the particles of a medium in which two sound waves (a), (b) propagate and the distance (x) travelled by the two waves in the same time interval so:

- (i) The ratio between the frequencies of the two waves  $\left(\frac{v_a}{v_b}\right)$  is ....
- $a)\frac{1}{1}$

ⓑ  $\frac{2}{1}$ 

- $\bigcirc \frac{1}{2}$
- (d)  $\frac{1}{4}$
- (ii) The ratio between the amplitudes of the two waves  $\binom{A_a}{A_b}$  is ...
- $\frac{1}{1}$

ⓑ  $\frac{2}{1}$ 

 $\bigcirc \frac{1}{2}$

- 22 Sound travels in air as ...........
  - a longitudinal waves
  - c longitudinal and transverse waves
- **b** transverse waves
- d electromagnetic waves
- The opposite figure represents a wave propagating in a rope, then this wave is .........

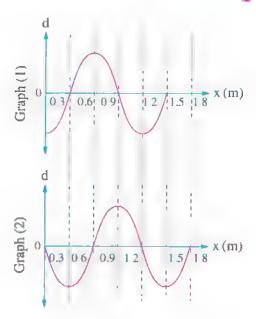

- (b) a longitudinal wave of wavelength y
- (c) a transverse wave of wavelength x
- d a transverse wave of wavelength y

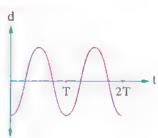

- What is the characteristic that describes all the longitudinal waves and does not describe all the transverse waves?
  - (a) They can be travelling waves.
  - b They require a medium in order to propagate.
  - c They transfer energy in the direction of their propagation.
  - d Their speed of propagation differs from medium to another.
- - d could be transverse or longitudinal of amplitude 2 cm
  - b is certainly not longitudinal and its amplitude is 2 cm
  - c could be transverse or longitudinal of amplitude 4 cm
  - d is certainly not transverse and its amplitude is 4 cm

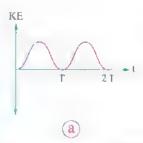

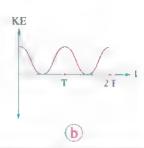

- \* Graph (2) represents the position of a travelling wave in a string after 0.025 s from its position that is represented in graph (1), then the frequency of the wave equals ........
  - (a) 7.5 Hz
  - (b) 10 Hz
  - (c) 15 Hz
  - **d** 30 Hz

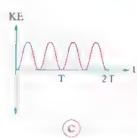

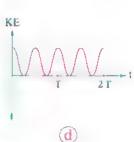

- Which of the following statements is correct for all transverse waves?
  - (a) They are electromagnetic waves.
  - Their speed in a medium equals the product of their frequency and wavelength.
  - © They can propagate through space.
  - d They cause vibrations of the medium atoms through which they propagate.
- A wave propagates in a string and the opposite graph represents the relation between the displacement (d) of one of the string particles about its equilibrium position and the time (t), which of the following graphs represents the relation between the kinetic energy (KE) of this particle and the time (t)?

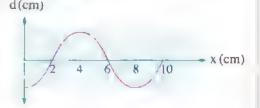

- When a pulse is made in a rope, the speed of the pulse along the rope
  - (a) remains constant
  - c increases

- (b) decreases
- d increases then decreases

- A transverse wave propagates through a thin thread at speed 300 m/s. If the distance between two successive crests is 3 m, so the wave frequency equals ...
  - (a) 0.01 Hz
- (b) 100 Hz
- (c) 300 Hz
- d 900 Hz
- 31) \* A wave of frequency 100 Hz is generated in a string, so it has a wavelength of 0.5 m, then:
  - (i) The wave speed through the string equals .....
- (a) 25 m/s (b) 50 m/s (c) 100 m/s
- (d) 200 m/s
- (ii) If the frequency increases to 300 Hz at constant speed, the wavelength
- (a) 0.03 m
- **b** 0.17 m
- © 3 m
- (d) 6 m
- 32 A girl stood on the beach to watch the waves. She observed that every two seconds four waves hit a rock in front of her where each wave has a length of 0.5 m, so the wave
  - (a' 0.2 m/s
- **b** 0.25 m/s
- c) 0.5 m/s
- (d. 1 m/s
- If the frequency of a wave in a given medium decreases to its half, then.

  - (a) its wavelength increases to the double (b) its wavelength decreases to the half
  - (c) its speed decreases to the half
- d its speed increases to the double
- The opposite graph represents the relation between the displacement of medium particles (d) and the propagation distance (x) of a transverse wave at a certain instant. If the frequency of this wave is 80 Hz, its speed of propagation equals .............

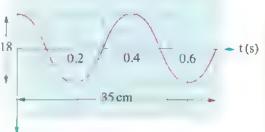

- (a) 0.64 m/s
- (b) 0.32 m/s
- 6.4 m/s
- d 3.2 m/s

The opposite graph represents the relation between the vertical displacement of one of the medium particles (d) and the time (t) for a wave, then:

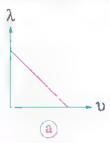

- (i) The amplitude of that wave is ............
- (a) 9 cm
- (b) 17.5 cm
- (c) 18 cm
- (d) 35 cm

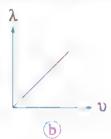

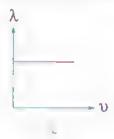

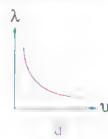

- (ii) The frequency of the wave is .............
- (a) 1.7 Hz
- (b) 2.5 Hz
- (c) 3.3 Hz
- (d) 5 Hz

- (iii) The propagation speed of the wave is
- (a) 0.5 m/s
- b 0.6 m/s
- (c) 50 m/s
- (d) 60 m/s
- 36 Which of the following graphs represents the relation between the wavelength ( $\lambda$ ) for multiple sound waves propagating in air and the frequency (v) for each of these waves?

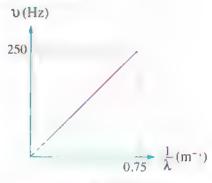

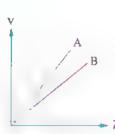

\* A sound source produces tones with different frequencies propagating in air, the opposite graph represents the relation between the frequency (0) and the reciprocal of wavelength  $(\frac{1}{1})$  for these waves, then the speed of the sound wave propagation through the air almost equals ......

- (a) 2 m/s
- (b) 50 m/s
- (c) 254 m/s
- d 333 m/s
- The opposite graph shows the relation between the speed (v) and the wavelength  $(\lambda)$  for two different waves of the same type (A and B) when they propagate through many different media, so -

- $a v_A > v_B$
- $b_{\nu_{\rm A}} < v_{\rm B}$
- (c)  $T_A = T_B$
- $(\mathbf{d}) T_{\mathbf{A}} > T_{\mathbf{R}}$
- Two laser rays, one of them is red and the other is green, propagate in space, so the two rays certainly have the same .......
  - (a) intensity
- (b) frequency
- c speed
- (d) wavelength

An electromagnetic wave of wavelength  $\lambda$  and frequency  $\upsilon$  propagates in air with speed c, so which of the following choices represents the wavelength and the speed of another electromagnetic wave that has frequency  $\frac{\upsilon}{2}$  and propagates in air?

The wavelength		The speed	
a	$\frac{\lambda}{2}$	$\frac{\mathbf{c}}{2}$	
Ъ	$\frac{\lambda}{2}$	С

### **Essay questions**

The opposite figure shows a pulse moving through a spring.

### Study the figure and answer the following questions:

- What is the type of the produced mechanical wave in the spring?
- 11) What is the direction of motion of the medium particles with respect to the direction of wave propagation?
- In a rainy day, a boy noticed that he saw the lightning before hearing the thunder, explain this observation.
- Two glass jars contain two alarm clocks. If one of them contains air and the other is evacuated from air, which of the two alarms can be heard? And why?

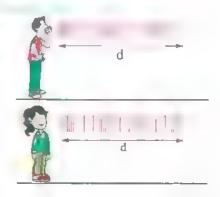

- Explain the following statements:
  - (1) Electromagnetic waves don't need a medium through which they can propagate.
  - 2. We see the light of the Sun and don't hear the sound of the explosions on its surface.
  - Astronauts use wireless devices to communicate on Moon.
- If a rope is fixed to the wall and its other terminal is being moved up and down so that a wave is produced in the rope as shown in the figure, so if you move your hand faster without changing the vertical displacement of your hand's motion or the tension force in the rope,

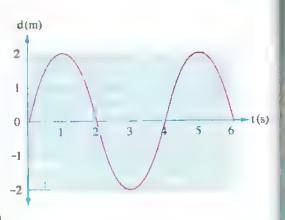

- The amplitude?
- (h) The wavelength?
- (d) The periodic time?
- (e) The wave speed?

- The frequency?
- The opposite figure shows the sound waves which are produced by a man and a girl:
  - (a) Which of the two sound waves is travelling faster? And why?
  - (b) Which of the sound waves has higher frequency? And why?

- The opposite graph shows the relation between the vertical displacement (d) and the time (t) of a wave motion which is formed in a rope:
  - (a) What is the type of the formed wave in the rope?
  - (b) Calculate the frequency of the wave.
  - (c) Plot using the same scale the relation
    between the displacement (d) and the time (t)
    for a wave that has double the frequency
    and half the amplitude of this wave.

## Answered in detail

### Choose the correct answer:

1 The opposite figure shows a transverse mechanical wave propagating in a medium from left to right, so in which direction the particle P moves at the shown instant?

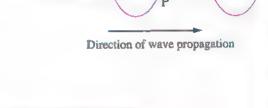

(b) Leftward

© Upward

**d** Downward

(a) 10 cm

**b** 20 cm

d(cm)
4
20 40 60 80 x(cm)

(c) 40 cm

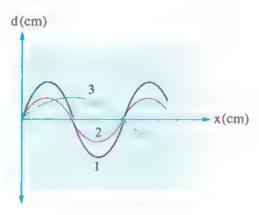

(d) 80 cm

- Two tones have frequencies 680 Hz and 425 Hz in air. If the wavelength of one of them is greater than the wavelength of the other wave by 30 cm, then the speed of sound in air equals ......
  - (a) 320 m/s
- (b) 330 m/s
- (c) 340 m/s
- (d) 544 m/s
- A boy heard the thunder 18.74998 s after seeing the lightning produced in a thunderstorm that was at a distance 6 km away, so the speed of sound in air was ............ (Given that: The speed of light in air =  $3 \times 10^8$  m/s)
  - (a) 360 m/s
- (b) 340 m/s
- © 330 m/s
- (d) 320 m/s

### Answer the following questions:

- The opposite graph represents the relation between the vertical displacement (d) and the propagation distance (x) for three waves (1, 2 and 3) where each one of them propagates separately in a tight string stretched by a fixed tension force. Rank these waves in a descending order according to:
  - (a) Wavelength.
  - (b) Frequency.

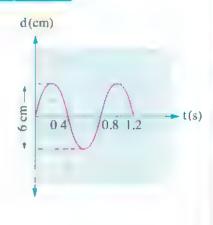

Test on Chapter

### **Wave Motion**

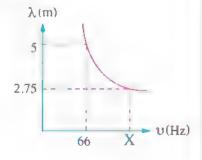

### Choose the correct answer (1:15)

	Amplitude (A) cm	Frequency (v) Hz
(a)	6	2.5

### Terrain female the following quartiess (16/10)

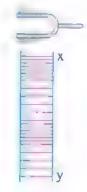

The opposite figure shows a pendulum that is displaced away from its equilibrium position to point x then left to swing, explain the energy transformations just after leaving the pendulum directly till it returns to its equilibrium position again.

Two light waves x, y, one is red and the other is blue, are propagating in different media. The opposite graph represents the relation between the wavelengths (λ) of the two waves and their speeds (v), then which of the two waves x, y is red? Explain your answer.

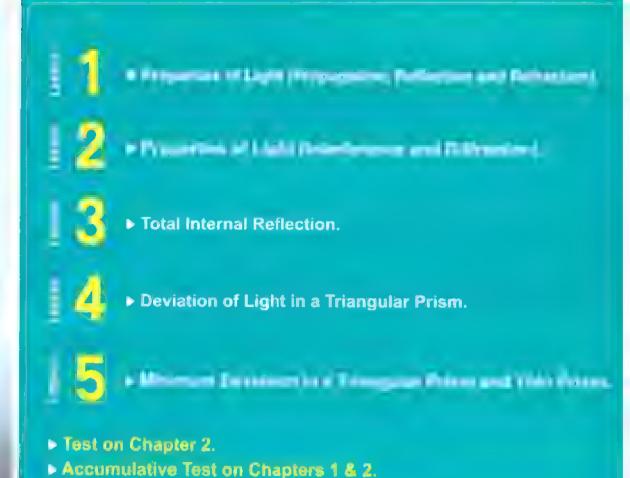

(18) A sound wave travels inside a glass tube from terminal x to terminal y as shown in the opposite diagram, describe how air molecules move inside the tube, with explanation.

# Chapter Two Light

# Chapter objectives

# By the end of this Chapter, the student should be able to:

- Mention the properties of light waves
- Discover the two laws of light reflection and light refraction
- Deduce Snell's law.
- Carry out an experiment to explain the light interference phenomenon and determine the wavelength of a monochromatic light
- Carry out an experiment to explain the occurrence of diffraction of light.
- Compare between the reflection of light, the refraction of light, the diffraction of light and the interference of light
- Identify the critical angle and the total internal reflection of light.

- Explain the working principle of optical fibers, the reflecting prism and the mirage phenomenon
- Differentiate between the normal prism and the thin prism
- Deduce the laws of a prism in the normal case and the special cases
- Carry out an experiment to trace the path of a light ray through a triangular prism
- Explain the dispersion of light by using a triangular prism
- · Deduce the dispersive power of a prism
- Acquire the skills of solving problems by using the mathematical relations in this chapter

Lesson One

Propagation Reflection and Refraction)

⊗ Sun is the main original energy source for life on Earth and light is the main way of transferring this energy to Earth.

# Wave nature of light

• In the study of the nature of light, physicists were divided into two groups:

# The first

They agree with Isaac Newton's idea which considers light as very tiny particles.

# The second:

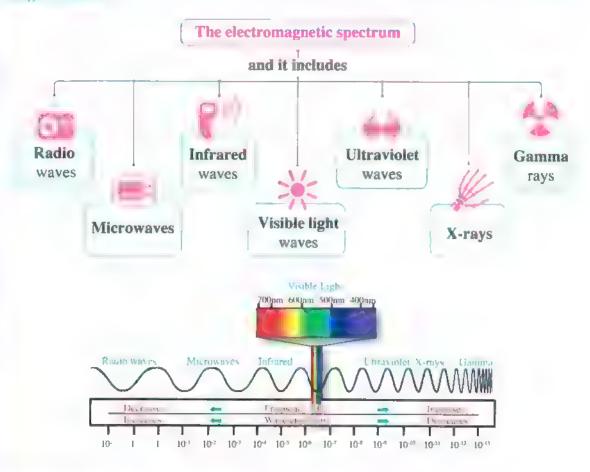

They agree with

Huygens' idea which
considers light as waves.

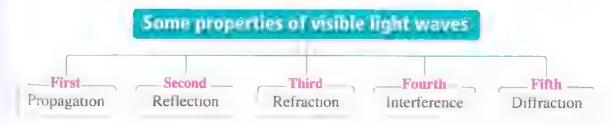

- However, modern physics (quantum physics) has proven the principle of dual nature of light, which states that the electromagnetic radiation has:
  - J. Wave nature: They are transverse electromagnetic waves.
  - 2. Particle nature: They consist of energy quanta that have particle nature called photons.
- Flectromagnetic waves have an extensive range of frequencies and wavelengths, this range is called:

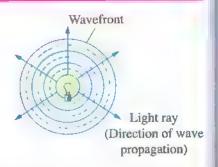

• From the figure, it is clear that visible light is a limited part of the electromagnetic spectrum and in the following, we will study some of its properties:

# First Light propagation

 Light that is originated from a point source propagates in a homogeneous medium in straight lines as concentric spheres of disturbances centered around the light source and that can be illustrated through representing the wavefronts as shown in the opposite diagram:

#### A wavefront

It is a surface in the path of wave motion on which the disturbances at every point have the same phase.

Wavefronts can be of three types depending on the source of light as follows:

### Plane wavefronts

Obtained when waves are coming from:

- A laser light source.
- A very distant light source (like the Sun).

### Spherical wavefronts

Obtained from a point source that sends out waves in three dimensions in a homogeneous medium as spherical wavefronts centered on the source.

# Cylindrical wavefronts

Obtained when waves are resulted from a longitudinal light source such as when light is passed through a fine rectangular slit.

# **Second** Light reflection

#### ○ Occurrence:

When light waves fall in a medium on a reflecting surface, they bounce back in the same medium and this phenomenon is known as light reflection.

Normal line Refected light ray Incident light ray Reflecting surface Point of incidence

# Light reflection, angle of incidence and angle of reflection can be defined as follows:

# Light reflection -

It is the bouncing back of light waves in the same medium when they encounter a reflecting surface.

# The angle of incidence $(\Phi_1)$

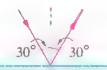

It is the angle between the incident light ray and the normal line on the reflecting surface at the point of incidence.

# The angle of reflection $(\phi_2)$

It is the angle between the reflected light ray and the normal line on the reflecting surface at the point of incidence.

# Tha reflection of light about two love, which are

Angle of incidence = Angle of reflection The first law

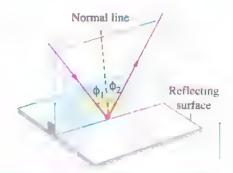

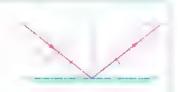

# The second law

The incident light ray, the reflected light ray and the normal line at the point of incidence all lie in the same plane which is perpendicular to the reflecting surface.

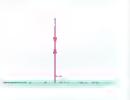

# Notes:

1 Light reflection can be represented using wavefronts as shown in the opposite figure:

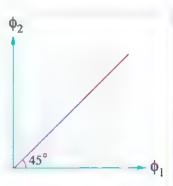

The light ray that falls perpendicular to a reflecting surface gets reflected on itself

breause the angle of incidence = The angle of reflection = Zero

(3) When plotting the relation between the angle of reflection (φ<sub>2</sub>) and the angle of incidence (φ<sub>1</sub>), we get a straight line and when the two axes have the same drawing scale, the straight line will make a 45° angle with the horizontal axis as in the opposite graph:

11 It is easier to see your reflected image on the glass window of a lighted room at night when the outside is dark than seeing your reflected image at daytime:

# Because

@ When outside of the room is dark!

The intensity of light passing from outside into the room is more lower than the reflected light from the inside,

When outside at the room is lighted:

The intensity of light passing from outside is larger than the reflected light intensity inside the room,

So

the person can see his image as a result of the light that is reflected on the glass inside the room.

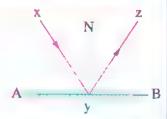

it is difficult for the person to see his reflected image on the glass.

The effect of entating the reflecting has foun and the incident light on

When a light ray (xy) is incident on
 a reflecting surface (AB), the ray gets reflected
 as shown in the opposite figure such that:

 Angle of incidence = Angle of reflection

When the reflecting surface rotates from plane AB with an angle  $\theta$  to be in plane  $\overrightarrow{AB}$  without changing the path of the incident ray (the normal line rotates with the same angle), that can be represented as follows:

1. The angle of incidence and the angle of reflection

Each of them increases by a value  $\theta$  Each of them decreases by a value  $\theta$ 

2. The angle between the meident ray and the reflected cas-

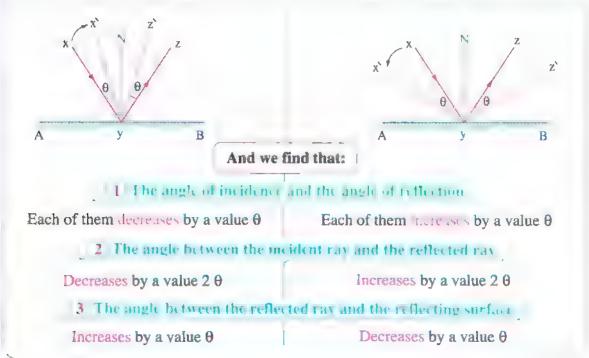

Increases by a value 2 0

Decreases by a value 2 0

3 The rotation of the reflected ray from its initial position. Rotates by a value 2  $\theta$  in the same direction of mirror rotation.

The state of the s

When the incident ray rotates with an angle  $\theta$  to take the path of xyz without changing the position of the reflecting surface, that can be represented as follows:

# Example 1

In the opposite figure, the angle of reflection equals ........

- (a) 30°
- (b) 45°
- © 60°
- d 90°

# Incident light ray Reflected light ray A Reflected light ray Reflecting surface

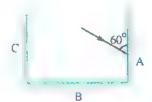

# Salution

- : The angle of incidence = The angle of reflection
- $\therefore$  The angle of reflection = 2  $\phi$
- : The angle between the normal line and the reflecting surface = 90°
- $\therefore 2 \phi + \phi = 90^{\circ}$
- ∴ φ = 30°
- $\therefore$  The angle of reflection = 2  $\phi$  = 2  $\times$  30 = 60°
- .. The correct choice is ©.

# Example 2

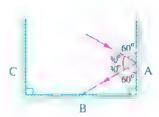

There mirrors A B and C, are perpendicular to each other. If a light ray talls on nurror A as shown in the agure trace the path of the light ray until its reflection at mirror C.

# Solution

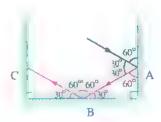

# **Q** Clue

When the ray falls on mirror A such that the angle between the ray and the surface of the mirror is 60°, it means that the angle of incidence is 30° and as the angle of incidence = The angle of reflection, so the angle of reflection on mirror A is 30°, then the ray falls on mirror B.

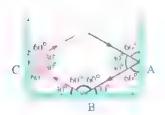

# **Q** Clue

When the ray falls on mirror B, the angle between the incident ray and the surface of the mirror equals 30°, hence the angle of incidence equals 60°, so the ray gets reflected from mirror B with an angle of reflection 60° to fall on mirror C.

# **Q** Clue

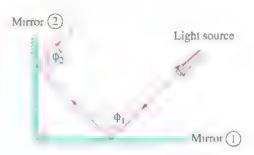

When the ray falls on mirror C the angle between the incident ray and the surface of the mirror equals 60°, therefore the angle of incidence equals 30°, then the ray gets reflected at mirror C with an angle of reflection 30°

What if the angle between the two mirrors A, B becomes equal to 120° without changing the direction of the incident light ray, what will be the angle of reflection of the ray from mirror A?

# Example 3

- (a) increase by 5°
- (b) increase by 10°
- c decrease by 5°
- d decrease by 10°

# Solution

$$: \phi_1 = \hat{\phi}_1$$

∴ When  $\phi_1$  increases by 5°,  $\dot{\phi}_1$  increases by 5°

$$\therefore \hat{\phi}_1 + \theta_1 = 90^{\circ}$$

:. When  $\dot{\phi}_1$  increases by 5°,  $\theta_1$  decreases by 5°

$$\theta_1 + \theta_2 = 90^{\circ}$$

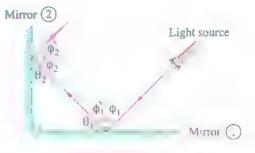

... When  $\theta_1$  decreases by 5°,  $\theta_2$  increases by 5°

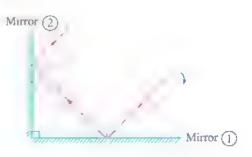

$$\because \theta_2 + \phi_2 = 90^\circ$$

∴ When θ<sub>2</sub> increases by 5°, φ<sub>2</sub> decreases by 5°

$$\Rightarrow \phi_2 = \hat{\phi}_2$$

- .. When \$\phi\_2\$ decreases by 5°, \$\hat{\phi}\_2\$ decreases by 5°
- .. The correct choice is (c).

What if the light source is kept fixed while rotating mirror ② by an angle of 5° such that the angle between the two mirrors increases, what happens to the value of angle  $\mathring{\phi}_2$ ?

# Example 4

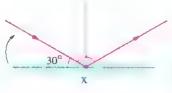

If the mirror gets rotated about point x in the direction shown in the figure 1, an angle of 10, the angle between the incident ray and the reflected ray becomes ........

(b) 135°

© 125°

(d) 115°

# Solution

- Before rotating the mirror:
  - : The angle of incidence  $(\phi_1)$  = The angle of reflection  $(\hat{\phi}_1)$
  - $\phi_1 = \phi_1 = 90 30 = 60^{\circ}$
- When rotating the mirror with 10°, both of the angle of incidence and the angle of reflection increases by the same value with which the mirror has rotated:

- $\therefore \ \phi_2 = \tilde{\phi}_2 = \tilde{\phi}_1 + \theta_{\text{rotation}} = 60^\circ + 10^\circ = 70^\circ$
- ... The angle between the incident ray and the reflected ray =  $\phi_2 + \tilde{\phi}_2 = 70 + 70 = 140^\circ$
- .. The correct choice is (a).

you are asked to determine the angle of rotation of the reflected ray from the initial position, what will be your answer?

# Test yourself

The opposite figure shows three mirrors A, B and C.

If a light ray falls on mirror A as shown in the figure,

trace the path of the ray till it gets reflected from mirror C.

- b will decrease
- © may increase or decrease
- d won't change

# Third Light infraction

 If you put a pencil in a glass of water and looked at it from the side, you will see the pencil as if it has been broken and this happens due to the refraction of light.

### @ Occurrence:

When a beam of parallel light rays falls on the interface (boundary surface) between two transparent media of different optical densities;

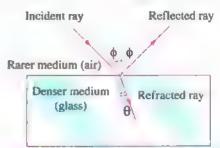

- Part of the light gets reflected in the first medium.
- Another part of light passes to the second medium deviated from its direction and this phenomenon is known as light refraction.
- The other part of light gets absorbed in the second medium.

### Optical density of a medium:

The ability of the medium to bend light rays when they enter into it.

😩 from the presidus, we can define hight refraction and the angle of refraction at fello Light refraction

It is a phenomenon that changes light direction when it travels slanted through the interface between two transparent media of different optical densities.

# The angle of refraction $(\theta)$

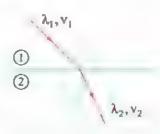

It is the angle between the refracted light ray and the normal line on the interface between the two media at the point of incidence.

# Why it happens?

- The refraction of light occurs due to the difference in the speed of light in the two media as a result of the difference in the optical densities of the two media.
- © Light refraction obeys two laws, which are:

#### First law

The ratio between the sine of the angle of incidence ( $\sin \phi$ ) in the first medium to the sine of the angle of refraction (sin  $\theta$ ) in the second medium equals the ratio of the speed of light (v<sub>i</sub>) in the first medium to the speed of light (v,) in the second medium which is a constant ratio for those two media and it is called dative refractive index from the first medium to the second medium  $(n_2)$ .

$$_{1}$$
 $n_{2} = \frac{\sin \phi}{\sin \theta} = \frac{v_{1}}{v_{2}} = \frac{\lambda_{1}}{\lambda_{2}}$ 

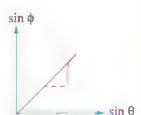

### Second law

The incident light ray, the refracted light ray and the normal line at the point of incidence all lie in the same plane which is perpendicular to the interface between the two media.

### From the first law

It is obvious that:  $\sin \phi \propto \sin \theta$ 

So, when plotting the relation between  $\sin \phi$  and  $\sin \theta$ , we get a straight line as in the opposite graph whose slope represents the relative refractive index between the two media.

Slope = 
$$\frac{\Delta \sin \phi}{\Delta \sin \theta} = {}_{1}n_{2}$$

From the previous, we can deduce that when a light ray falls on the interface between two transparent media such that it travels from:

An Aв. An optically optically optically optically To raret denser denser rarer medium medium medium medium

Such as

From air to glass

From glass to air

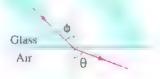

# So, the light ray is refracted (bent)

toward the normal on the interface, hence:

The angle of incidence  $(\phi)$  > The angle of refraction  $(\theta)$ 

away from the normal on the interface, hence: The angle of incidence  $(\phi)$  < The angle of refraction  $(\theta)$ 

# Thur factors affecting

djeg metoderj mofenodicu, jiselani, kozumensi, frenimismilist

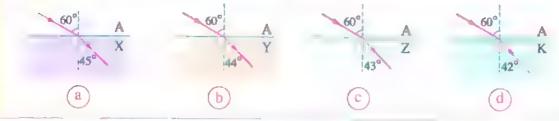

- 1. The types of the two media (their optical densities).
- 2. The wavelength of the incident light ray.

# Test yourself

### \* Choose the correct answer:

The four following figures represent four rays of a light that has a wavelength  $\lambda$  travelling from medium A to other four different media X, Y, Z and K each one at a time. In which of these media (X, Y, Z or K) the light ray will have the longest wavelength?

# The absolute refractive index of a mediu

 If a light ray passes from space or air into another transparent medium (given that the speed of light in air is nearly equal to its speed in space):

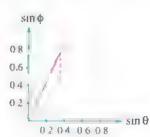

# From the previous, we can deduce that:

The absolute refractive index of any medium is always greater than one " the speed of light in space or air is a universal constant that equals to  $3 \times 10^8$  m/s and it is greater than its speed in any other medium.

The refractive index has no measuring units because it is a ratio between two similar physical quantities having the same measuring unit.

The speed of light in a medium is inversely proportional to the absolute refractive index of this medium  $(v \propto \frac{1}{n})$ .

When plotting the relation between (sin φ) for a light ray in air and  $(\sin \theta)$  in any other medium, we get a straight line as in the opposite graph whose slope is always greater than one and represents the absolute refractive index (n) for this medium.

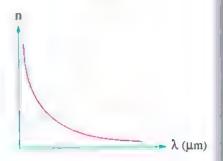

# The factors of feeting this absolute defraction index of a median

1. The type of medium material:

As the optical density of the medium increases its refractive index increases.

2. The wavelength of the incident light ray:

The refractive index of a medium decreases as the wavelength of the incident light increases and the opposite graph represents the relation between the absolute refractive index (n) of one type of glass and the wavelength (\(\lambda\)) of the light passing through it.

the relative refractive index for two media and their absolute refractive indices:

$$\therefore n = \frac{c}{v}, v = \frac{c}{n}$$

$$\therefore \frac{\mathbf{v_1}}{\mathbf{v_2}} = \frac{\mathbf{n_2}}{\mathbf{n_1}}$$

$$\cdots 1 n_2 = \frac{v_1}{v_2}$$

$$\Delta_{-1} n_2 = \frac{n_2}{n_1}$$

The relative refractive index i.e. from the fust medium to the second medium

The absolute refractive index of the second medium + that of the first medium

 $n_1$ 

And, accordingly the relative refractive index from the second medium to the first medium can be obtained from the relation:  $n_1 = \frac{n_1}{n_2} = \frac{1}{n_1}$ 

From the previous, we can compare between the relative retractive index media and the absolute refractive index of a medium as follows:

# Relative refractive index between two media

# Absolute refractive index of a medium

Illustrative diagram

Medium (1 Medium (2

# Concept

The ratio of the sine of the angle of incidence in the first medium to the sine of the angle of refraction in the second medium.

The ratio of the sine of the angle of incidence in space or air to the sine of the angle of refraction in the medium.

(or,

The ratio of the speed of light in the first medium to the speed of light in the second medium.

The ratio of the speed of light in space or air to the speed of light in the medium.

# Mathematical relation

$$_{1}n_{2} = \frac{\sin \phi}{\sin \theta} = \frac{v_{1}}{v_{2}} = \frac{\lambda_{1}}{\lambda_{2}}$$

$$n = \frac{\sin \phi}{\sin \theta} = \frac{c}{v} = \frac{\lambda_{air}}{\lambda_{medium}}$$

# Magnitude

Might be less or greater than one

Always greater than one

# The factors on which it depends

- The wavelength of the incident light.
- The wavelength of the incident light.
- The types of the two media.
- The type of medium.

# Measuring unit

None of them has a measuring unit since each of them is a ratio between two similar physical quantities that have the same measuring unit

# Snell's law

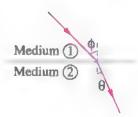

• From the first law of refraction:

$$\therefore n_2 = \frac{n_2}{n_1}$$

$$\therefore \frac{\sin \phi}{\sin \theta} = \frac{n_2}{n_1}$$

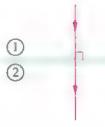

$$\begin{array}{ccc}
n & \sin \phi &= n, \sin \theta \\
& & & & \\
\end{array}$$

# Notes

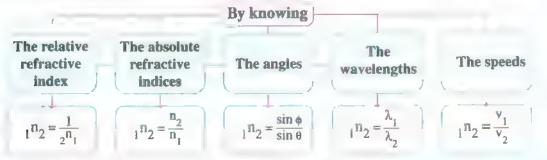

(1) The light ray that falls perpendicularly on the boundary between two transparent media, doesn't suffer any refraction because since the angle of incidence equals zero ( $\phi = 0^{\circ}$ ) and according to Snell's law ( $n_1 \sin \phi = n_2 \sin \theta$ ),  $n_2 \sin \theta = 0$ , hence the angle of refraction equals zero ( $\theta = 0^{\circ}$ ):

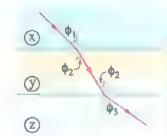

# Note that:

$$\lambda_1 \neq \lambda_2$$
  $v_1 \neq v_2$   $v_1 = v_2$   $\theta = 0$   $\phi = 0$ 

(2) The relative refractive index from the first medium to the second medium (1n2) can be calculated as follows:

(3) When the light ray passes successively through three media (x), (y) and (z) of refractive indices n<sub>x</sub>, n<sub>y</sub> and n<sub>z</sub> respectively, the angle φ<sub>3</sub>;

- depends on  $n_x$ ,  $n_z$  and  $\phi_1$
- doesn't depend on n

# Since:

$$\therefore n_x \sin \phi_1 = n_y \sin \phi_2$$

$$\therefore$$
  $n_v \sin \phi_2 = n_z \sin \phi_3$ 

From equations (1) and (2):

$$\therefore n_x \sin \phi_1 = n_z \sin \phi_3$$

$$\therefore \sin \phi_3 = \frac{n_x}{n_z} \sin \phi_1$$

This also holds true for more than three media when a light ray passes successively through them.

When a light ray travels from medium (1) to medium (2):

$$n_1 \sin \phi = n_2 \sin \theta$$
,  $\sin \theta = \frac{\pi_1}{n_2} \sin \phi$ 

And if

$$n_1 > n_2$$

 $n_1 < n_2$ 

Then

$$\phi < \theta$$

 $\phi > \theta$ 

And when mereasing the angles of incidence in with a given value, the angles of refraction ( $\theta$ ) increase with

# . A greater value

A smaller value

Where:

$$\frac{n_1}{n_2} > 1$$

Where:

$$\frac{n_1}{n_2} < 1$$

# Hamale 1

If the absolute refractive index of water is \(\tau\) and the absolute refractive index of glass is 🗦 , calculate:

- (a) The relative refractive index from water to glass.
- (b) The relative refractive index from glass to water.

# Solution

$$n_w = \frac{4}{3}$$
  $n_g = \frac{3}{2}$   $n_g = ?$   $n_w = ?$ 

$$(a)_{w} n_{g} = \frac{n_{g}}{n_{w}} = \frac{\frac{3}{2}}{\frac{4}{3}} = \frac{9}{8} = 1.125$$
  $(b)_{g} n_{w} = \frac{n_{w}}{n_{g}} = \frac{\frac{4}{3}}{\frac{3}{2}} = \frac{8}{9} = 0.889$ 

$$(h, gn_w = \frac{n_w}{n_g} = \frac{\frac{4}{3}}{\frac{3}{2}} = \frac{8}{9} = 0.889$$

$$_{g}n_{w} = \frac{1}{w_{g}^{n}} = \frac{1}{\frac{9}{8}} = \frac{8}{9} = 0.889$$

you are asked to calculate the ratio between the speed of light in water to its speed in glass, what will be your answer?

# Example 2

A light ray of wavelength 589 nm is incident in air on the surface of a glass plate of refractive index 1.52 at an angle of incidence  $30^\circ$ , calculate

- (a) The angle of refraction of the ray.
- (b) The speed of light inside the glass.
- (c) The wavelength of light inside the glass.

(The speed of light in air =  $3 \times 10^8$  m/s)

# Salution

$$\lambda_a = 589 \text{ nm}$$
  $n = 1.52$   $\phi = 30^{\circ}$   $c = 3 \times 10^8 \text{ m/s}$   $\theta = ?$   $v = ?$   $\lambda_g = ?$ 

(a) 
$$n = \frac{\sin \phi}{\sin \theta}$$
,  $\sin \theta = \frac{\sin \phi}{n} = \frac{\sin 30}{1.52}$ 

$$\therefore \theta = 19.2^{\circ}$$

(b) 
$$n = \frac{c}{v}$$
  
 $v = \frac{c}{n} = \frac{3 \times 10^8}{1.52} = 1.97 \times 10^8 \text{ m/s}$ 

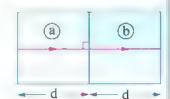

$$(c) : v_a = v_g \qquad , \qquad \therefore \frac{c}{\lambda_a} = \frac{v}{\lambda_g} \qquad , \qquad \therefore n = \frac{\lambda_a}{\lambda_g}$$

$$\lambda_g = \frac{\lambda_a}{n} = \frac{589}{1.52} = 387.5 \text{ nm}$$

the angle of incidence of the light ray on the surface of glass is changed, which of the previously calculated values in (a), (b) or (c) will change?

# Example 3

The opposite figure shows a light ray falling perpendicular on the interface from medium a to another medium b, if the number of light waves in medium a equals  $10^{\circ}$  waves and the number of light waves in medium b equals  $1.5 \times 10^{5}$  waves, find the relative refractive index  $a^{\circ}b$ 

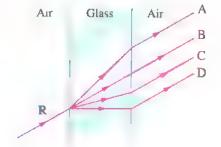

# Solution

$$N_a = 10^5$$
  $N_b = 1.5 \times 10^5$   $an_b = ?$ 

$$\lambda = \frac{x}{N}$$
,  $\lambda_a = \frac{d}{10^5}$ ,  $\lambda_b = \frac{d}{1.5 \times 10^5}$ 

$$_{a}n_{b} = \frac{v_{a}}{v_{b}} = \frac{\lambda_{a}}{\lambda_{b}} = \frac{d \times 1.5 \times 10^{5}}{10^{5} \times d} = 1.5$$

# Example 4

- (a) A
- **(b) B**
- © C
- $\bigcirc$  D

# Solution

$$n_{glass} > n_{air}$$

$$n_{glass} = \frac{\sin \phi_{air}}{\sin \phi_{glass}}$$

$$\cdot \phi_{air} > \theta_{glass}$$

# **Q** Clue

To determine the correct path of the light ray, the normal lines to the boundary surfaces must be drawn at each point of incidence for determining either if the ray passes in a straight line, bends towards the normal or away from it.

i.e., the light ray makes an angle with the normal in air greater than the angle that it makes in glass.

- .. At the boundary surface between air and glass, the light ray refracts towards the normal and at the boundary surface between glass and air, the light ray refracts away from the normal.
- ... The correct path for the light ray is C
- .. The correct choice is ©.

you assumed that the sheet is made of diamond, bearing in mind that the refractive index of diamond is greater than the refractive index of glass, will the angle at which the light ray emerges into air change?

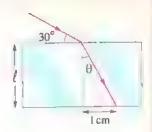

# Test yourself

Answered

A light ray falls on the surface of a glass of refractive index 1.5 at an angle of incidence 60°, if a small part of the light gets reflected and another part gets refracted, calculate the angle between the reflected and the refracted light rays.

# **Essay questions**

The opposite figure shows the reflection of a light ray. If the angle of incidence is increased, does the reflected ray change its path?

And if it does, in which direction it will be changed? Explain your answer.

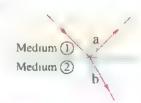

2 The opposite figure shows a light ray which is falling perpendicularly from air onto the surface of water. Find the value of the angle of refraction with explaining your answer.

- 3 A light ray travelled from a medium of refractive index n<sub>1</sub> to another medium of refractive index n<sub>2</sub>. Show by drawings the path of the light ray through the two media if:
  - (a)  $n_2 < n_1$
- (b)  $n_2 > n_1$

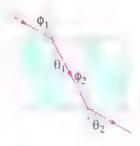

- Explain the following statements:
  - If It is easier to see your reflected image on the glass of a window from the inside of a lighted room at night when the outside is dark than seeing your image at daytime when there is light outside.
  - 2 The absolute refractive index for any medium is always greater than one however the relative refractive index may be less or greater than one.
- When a wave of light moves from medium (1) to another medium (2) for which the ratio between the absolute refractive indices is  $\frac{n_2}{n_1} > 1$ , what happens to each of the frequency, the wavelength and the speed of the wave?
- The opposite figure shows the transmission of a light wave between two media 1 and (2, what will happen to each of angle a and angle b if the angle of incidence increases?

The opposite figure shows a red light ray falling on a semi-circular prism. Will the angle of refraction change if a blue light ray is used instead of the red light? Explain your answer.

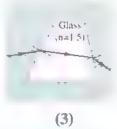

8) The opposite figure shows the path of a light ray falling from air on a glass block. Prove that:  $\phi_1 = \theta_2$ 

Study the following figures and answer:

Which of these figures represents the falling of a light ray from a liquid having the following refractive indices?

(a) 1.5

(b) 13

(c) 1.6

# Questions that measure him had all the land

### Choose the correct answer:

1 In the opposite figure, a light ray is incident on mirror M<sub>1</sub> parallel to mirror M<sub>2</sub>, hence the ray gets reflected from mirror M<sub>1</sub> to fall on mirror M<sub>2</sub> and get reflected from it parallel to mirror M<sub>1</sub>, so angle θ equals ...

The opposite figure shows a man looking constantly at a metal coin that is placed at the bottom of a container filled with water up to level x, hence the coin seems to him at specific position (a). When water is let to spill out gradually from the container till the surface of water becomes at level y, the man will see the image of the coin ............

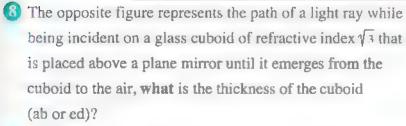

Screen

a) rising up gradually stable at the bottom of the container (b) descending gradually

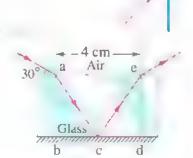

d remained stable at its level (a)

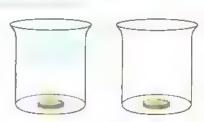

# Answer the following questions:

In the opposite figure, two light rays intersect at a point on a vertical screen. If a glass plate is put in front of the screen in the path of the two rays, will the two rays intersect on the screen? Explain your answer.

In the opposite figure, two metal coins were put in two cups such that one coin was put in an opaque cup containing water and the other in a similar empty cup, so if you looked at the two coins with a certain inclination angle and saw a part of the coin which is in the cup containing water and didn't see the coin in the empty cup, how can you explain that?

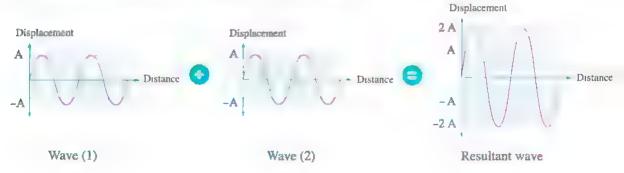

# Interference of waves

The phenomenon of wave interference occurs when two waves that are propagating in the same medium and have been produced from two coherent sources (sources that have the same frequency, amplitude, wavelength and phase) overlap (principle of superposition) leading to;

1 Are altered and in the intensity of the two waves at some positions "

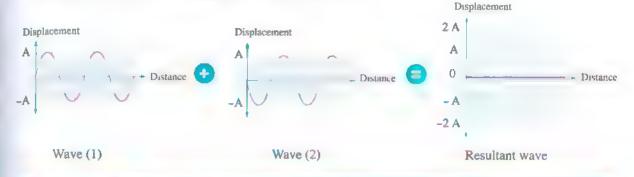

Interest and a result of the overlap (superposition) of a crest from one wave with a crest from the other wave or a trough from one wave with a trough from the other wave.

This can be represented graphically as follows:

A cake less in the intensity of the two waves at some other positions "active to the overlap (superposition) of a crest from one wave with a trough from the other wave.

This can be represented graphically as follows:

### Fourth Light interference

• To study the interference of light, we carry out the following experiment:

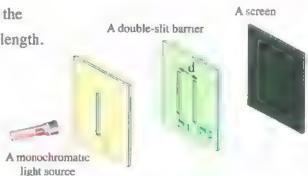

## Loin . Leding . double still - ... up. at

### **Objectives:**

- 1. Proving the wave nature of light.
- 2. Investigating the phenomenon of light interference.
- Betermining the wavelength of a monochromatic (single wavelength) light.

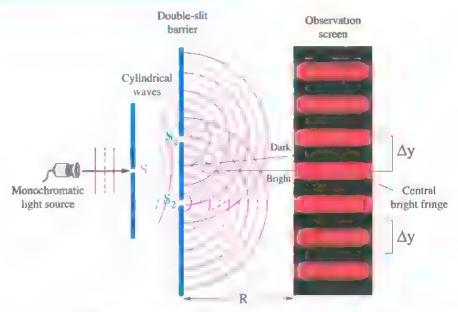

### 🖟 pparatus:

- A monochromatic light source so that the overlapping waves have the same wavelength.
- A barrier with a rectangular narrow slit "S" positioned at equal distances from both slits S<sub>1</sub>, S<sub>2</sub> and at an appropriate distance from the light source.

- A barrier with two rectangular narrow slits (S and S) to act as a double-slit separated by a distance d.
- A screen to receive the interference pattern.

### teps, observations and conclusions:

Schematic diagram of Young's double-shit experiment

- When turning on the light source, the light waves pass from slit in the form of cylindrical waves, where:
  - The continuous) curves represent wave crests.
  - The dashed curves represent wave troughs.
- ¹ The two slits (§, §) are adjusted, so when the light waves reach them, they will be at the same cylindrical wavefront, so they act as two coherent sources, . They produce two coherent waves having the same frequency, amplitude and phase.
- The two waves from S and S propagate beyond the double slit barrier and when they reach the last screen, they interfere with each other and give a pattern of interference (as shown in the previous figure) and this phenomenon is known as the man it can be defined as follows:

### Interference pattern:

It is a pattern of bright fringes (maxima) punctuated with dark fringes (minima) resulted from the superposition of the light waves that are produced from two coherent sources.

### Interference of light:

It is the phenomenon of superposition of the light waves that are produced from two coherent sources causing reinforcement in light intensity in some positions (bright fringes) and weakness in light intensity in other positions (dark fringes).

Measure the distance between the centers of two successive fringes ( $\Delta y$ ) of the same kind (bright or dark), hence with knowing each of  $\Delta y$ , R and d, the wavelength of the used light can be determined from the relation:  $\Delta y = \frac{\lambda R}{d}$ 

Where  $(\lambda)$  is the wavelength of the used light, (R) is the distance between the double-slit barrier and the observation screen and (d) is the distance between the two slits.

### As studying Young's double-slit experiment, we find that:

- (1) Conditions for the occurrence of light interference:
  - The used light source must be monochromatic.
  - Slit must be at equal distances from the two slits \, \, for making the double-slit work as two coherent light sources.
- (2) The interference of waves is of two types:

### Constructive interference

Reinforcement in the intensity of the light in some regions (bright fringes) as a result of the overlapping of a crest of one wave with a crest of another wave or a trough of one wave with a trough of another wave.

#### Destructive interference

• Weakness in the intensity of the light in some regions (dark fringes) as a result of the overlapping of a crest of one wave with a trough of another wave.

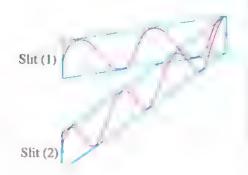

### Its condition

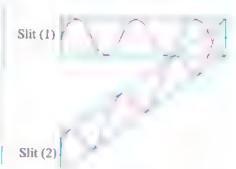

It produces

- The path difference of the two interfered waves =  $m\lambda$
- The path difference of the two interfered waves =  $(m + \frac{1}{2}) \lambda$

Where: m is the order of the fringe which is an integer number  $(0, 1, 2, ...), \lambda$  is the wavelength of the used light.

Representation

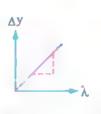

### The fratory affecting

successive fringes of the same kind:

The wavelength of the used light "directly proportional".

$$=\frac{\Delta(\Delta y)}{\Delta \lambda}=\frac{R}{d}$$

The distance between the observation screen and the double-slit barrier "directly proportional"

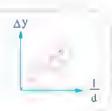

$$= \frac{\Delta(\Delta y)}{\Delta R} = \frac{\lambda}{d}$$

$$\Delta y = \frac{R}{d}$$

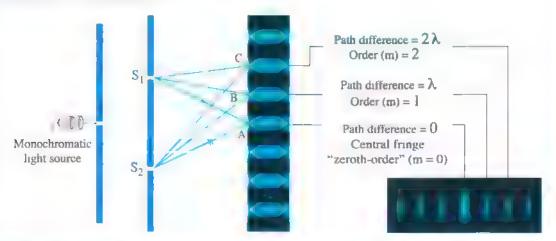

The distance between the two slits "inversely proportional".

Slope = 
$$\frac{\Delta(\Delta y)}{\Delta(\frac{1}{d})} = \lambda R$$

# Notes:

(1) In the following diagram:

· Point A represents the center of the central fringe (always bright), at which:

The path length of the first wave resulted from slit S<sub>1</sub>

The path length of the second wave resulted from slit S,

### the center of the first bright fringe, at which:

The path length of the first wave resulted from slit S.

The path length of the second wave resulted from slit S, by a value of  $\lambda$ 

· Point C represents the center of the second bright fringe, at which:

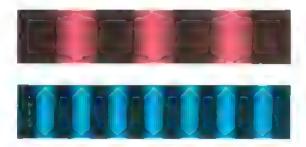

The path length of the first wave resulted from slit S<sub>1</sub>

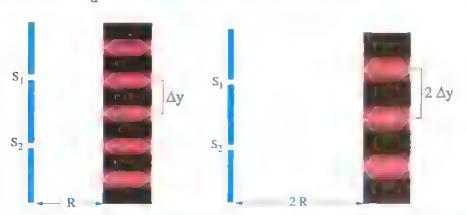

The path length of the second wave resulted from slit S, by a value of 2  $\lambda$ 

And existence that the path of the ence between two over apping a vive can be determined at the centers of the rest of interference tringes.

In Young's double-slit experiment, it is preferable to use a light of relatively long wavelength to make the distance between the interference fringes relatively large, hence the interference pattern becomes easier to be observed as shown in the following figure where  $\lambda_h < \lambda_r$ 

When increasing the distance between the double-slit barrier and the observation screen (R), the distance between the interference fringes increases according to the relation  $(\Delta y = \frac{\lambda R}{d})$  as represented in the following figure:

### Example 1

In the doubte-slit experiment, if the distance between the two narrow ic, langular stits war 0.15 mm, the distance between the downs slit barrier and incobservation screen was 🧑 in and the distance between the centers of two successive bright tringes was 6.3 cm, calculate the wavelength of the a clim morniomatic aght source

### Solution

$$d = 0.15 \text{ mm}$$

$$R = 75 \text{ cm}$$

$$d = 0.15 \text{ mm}$$
  $R = 75 \text{ cm}$   $\Delta y = 0.3 \text{ cm}$ 

$$7 = ?$$

$$\Delta y = \frac{AR}{d}$$

$$\lambda = \frac{d\Delta y}{R} = \frac{0.15 \times 10^{-3} \times 0.3 \times 10^{-2}}{75 \times 10^{-2}} = 6 \times 10^{-7} \text{ m} = 0.6 \text{ } \mu\text{m} = 6000 \text{ Å}$$

the observation screen is displaced away from the double-slit barrier, what will happen to the distance between any two successive dark fringes?

### wemple 2

The opposite figure represents the interference

pattern of Young's experiment which was conducted with a light of wavelength 5000 A and an observation screen at distance 120 cm

from the double-slit. If the distance between the central fringe (0) and the fourth bright fringe (4) was 0.8 cm, calculate the distance between the two slits.

### Solution

$$x = 0.8 \text{ cm}$$
  $N = 4$   $\lambda = 5000 \text{ Å}$   $R = 120 \text{ cm}$   $d = ?$ 

$$\Delta y = \frac{x}{N} = \frac{0.8 \times 10^{-2}}{4} = 2 \times 10^{-3} \text{ m}$$

$$\Delta y = \frac{\lambda R}{d}$$

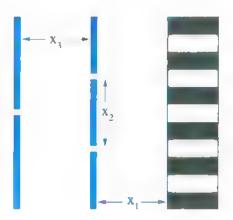

$$\mathbf{d} = \frac{\lambda R}{\Delta y} = \frac{5000 \times 10^{-10} \times 120 \times 10^{-2}}{2 \times 10^{-3}} = 3 \times 10^{-4} \text{ m}$$

### Example 3

The opposite figure represents a setup of the double-slit experiment, which of the distances that are drawn in the figure has to be reduced to make the interference pattern become more obvious?

$$\mathbf{a} \mathbf{x}_1$$

$$(\mathbf{d} \ \mathbf{x}_1, \mathbf{x}_3)$$

### Solution

By decreasing the distance between the two rectangular narrow slits ( $d = x_2$ ), the distances between the centers of every two identical successive fringes ( $\Delta y$ ) increases, according to the relation;  $\left(\Delta y = \frac{\lambda R}{d}\right)$ , hence the fringes become easier to be seen.

.. The correct choice is b.

# Test yourself

A monochromatic light of wavelength  $66 \times 10^{-8}$  m fell on two slits of separation distance  $11 \times 10^{-4}$  m, so interference fringes were formed on an observation screen which was at a distance 1 m from the double-slit barrier.

Calculate the distance between the centers of two successive fringes of the same type.

Choose the correct answer:

The opposite figure represents the interference pattern obtained in a double-slit experiment when using a light of wavelength  $\lambda$ , so if a light of wavelength  $\frac{4}{5}\lambda$  is used, the distance between the centers of the central fringe and the first bright fringe becomes

- a 0.4 mm
- (b 0.75 mm
- 'c 1.25 mm
- (d) 1.5 mm

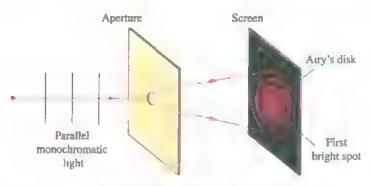

### Fifth 🔚

## Light diffraction

When a monochromatic light is incident on a small aperture of a barrier or a circular aperture whose size is small compared to the wavelength of the incident light, a bright spot of light which is called A appears at the center surrounded by alternated progressively fainter bright and dark rings. This phenomenon happens as a result of the context of

Diffraction on a circular aperture

### What happens can be explained as follows:

When monochromatic light waves fall on a sharp edge or on a circular aperture of a barrier whose size is small compared to the wavelength of the incident light:

- They change their direction of propagation (diffract).
- Each point on the wavefront of the wave passing through the aperture acts as a secondary light source that forms waves of the same wavelength and phase.
- These waves interfere (superpose) with each other behind the aperture giving diffraction fringes.

### Diffraction fringes pattern

It is a pattern of alternate bright and dark regions produced due to the superposition of the diffracted light waves as passing from an aperture of a very small size or falling on a sharp edge.

### Erom the previous, light diffraction can be defined as follows:

### Diffraction of light

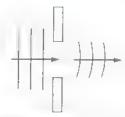

It is the phenomenon of changing the direction of light waves propagation through the same medium when they pass through a very narrow aperture or fall on a sharp edge in which the superposition of waves leads to the formation of bright and dark fringes.

### The condition of a clear appearance of light diffraction:

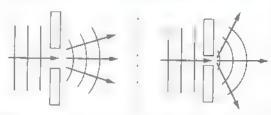

The wavelength of the light wave has to be close in size to the dimensions of the aperture, so if the aperture size is:

much larger than the wavelength of light

The diffraction doesn't appear.

▶ The diffraction appears and becomes more clearer by decreasing the aperture size.

# Notes:

(1) The shape of the diffraction fringes depends on the shape of the narrow slit on which light is incident, so when light falls on a rectangular narrow aperture, it suffers diffraction and

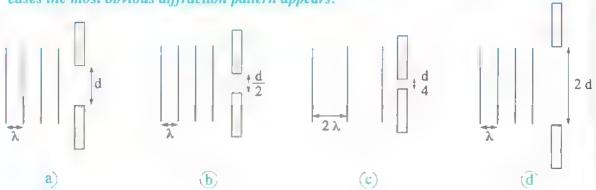

- the diffraction fringes appear as a pattern having a central wide bright fringe surrounded laterally with progressively fainter and narrower distributed bright fringes punctuated with dark fringes as shown in the figure.
- 12) The range of wavelengths of visible light extends from 400 nm to 700 nm which are very short wavelengths so that light diffraction doesn't appear in our daily life because visible light needs very small aperture sizes for the appearance of light diffraction patterns.
- From the study of light interference and light diffraction phenomena, it was found that there is no big difference between the light interference model and light diffraction model be an each of them is a wave phenomenon which results from the superposition of waves.

### Enrichment information

A diffraction grating is an optical component made of a sheet having a large number of evenly spaced parallel slits that reaches 10000 slits separated by distances that could reach  $10^{-6}$  m which produces a diffraction pattern.

### Example

In each of the following figures, a wave encounters a narrow slit so in which of these cases the most obvious diffraction pattern appears?

### Solution

As the size of the slit through which the wave passes decreases compared to the wavelength, diffraction becomes more obvious.

.. The correct choice is ©.

### Test yourself

Choose the correct answer:

Which of the following figures shows the pattern of light diffraction through a circular aperture?

Trom the previous, we can compare between interference and diffraction as follows:

#### Interference

- It appears when using a double-slit.
- Bright and dark fringes that are equally spaced are formed.
- Light intensities at the centers of the bright fringes are equal.

#### Diffraction

- It appears when using a single narrow slit.
- Central wider bright fringe surrounded by less wide bright fringes are formed.
- Light intensities at the centers of the bright fringes get dimmer as we get away at the two sides from the central fringe.

(2) The phenomena of reflection, retraction interference and diffraction of light waves can be summed up as follows:

	Scientific concept	The bouncing of light waves in the same medium when they meet a reflecting surface.	
Reflection	Occurrence	At the reflecting surface in the same medium.	
	Condition	The light waves fall on a reflecting surface.	
	Scientific concept	The change in the direction of light path when it passes the separating surface between two transparent media which are different in the optical density.	
leanton	Occurrence	At the boundary surface between two transparent media which are different in the optical density.	
_	Condition	The two transparent media have different optical densities.	
	Scientific concept	The superposition of light waves produced from two coherent sources, producing reinforcement (bright fringes) some regions and weakness (dark fringes) in other regions	
Interference	Occurrence	In the same medium when the light encounters a double-slit.	
	Condition	<ul> <li>Using a monochromatic light source.</li> <li>Slit S must be at equal distances from the other two slits (S<sub>1</sub>, S<sub>2</sub>), hence the double-slit works as two coherent light sources.</li> </ul>	
Diffraction	Scientific concept	The change in the direction of the waves path in the same medium when passing through a narrow slit or an aperture whose dimensions are comparable to the wavelength of the light waves leading to the superposition of waves and the formation of bright fringes and dark fringes.	
	Occurrence	At a slit or a sharp edge in the same medium.	
	Condition	The size of the slit must be near in size to the wavelength of the light.

(d D

• Previously, we have explored the behavior of light rays when they encounter the boundary between two different media. We have learned that when a light ray is incident upon this boundary, its direction is altered as it passes through the second medium, a phenomenon known as

However, in some cases, all of the light ray is reflected back into the first medium, a process called the second of the light ray is reflected back into the first medium, a process called the second of the light ray is reflected back into the first medium, a process called the second of the light ray is reflected back into the first medium, a process called the second of the light ray is reflected back into the first medium, a process called the second of the light ray is reflected back into the first medium, a process called the second of the light ray is reflected back into the first medium, a process called the second of the light ray is reflected back into the first medium.

# Jutal Internal inflection

#### ⊕ O← if rence;

- When a ray of a monochromatic light falls from an optically denser medium (such as water) on the boundary surface with an optically less dense (rarer) medium (such as air), there will be some possibilities:

If the angle of incidence equals zero
 (the light ray falls perpendicular on the boundary surface (φ = 0))

The light ray passes into the optically rarer medium (air) without any refraction  $(\theta = 0)$ 

If the angle of incidence is increased slightly to be greater than zero (the light ray falls at an angle on the boundary surface (\$\phi > 0\$))

The light ray passes into the optically rarer medium (air) refracted away from the normal on the boundary surface where:  $n_1 \sin \phi = n_2 \sin \theta$ 

By increasing the angle of incidence
 of light gradually

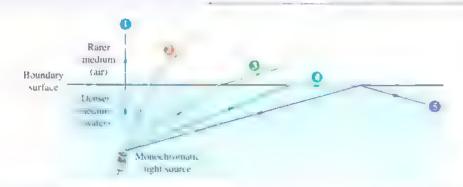

The angle of refraction ( $\theta$ ) in the optically rarer medium (air) increases gradually as:  $n_t \sin \phi = n_x \sin \theta$ 

When the angle of incidence reaches
a definite value that is known as the
critical angle (φ<sub>c</sub>)

The light ray gets refracted tangent to the boundary surface *i.e.*, the angle of refraction of the light ray ( $\theta$ ) equals 90°, so:  $n_0 \sin \phi_0 = n_2$ 

When the angle of incidence becomes greater than the critical angle  $(\phi > \phi_c)$ 

The light ray gets reflected back in the optically denser medium (water) so that the angle of incidence = The angle of reflection

From the previous, we can define each of the critical angle between two media and the total internal reflection as follows:

The critical angle between two media  $(\phi_c)$ : It is the angle of incidence of the light ray in the denser medium which leads to a refraction angle of 90° in the rarer medium.

The total internal reflection:
It is the reflection of light ray in the denser medium when it is incident at an angle that is greater than the critical angle between the two media.

# Including the relation behinder the orbital region and the inferior

When a light ray passes from an optically denser medium (n<sub>1</sub>) to an optically rarer medium (n<sub>2</sub>), Snell's law is applied:

$$n_1 \sin \phi = n_2 \sin \theta$$

If the light ray falls with an angle of incidence that equals the critical angle  $(\phi_c)$  between the two media, it gets refracted tangent to the boundary surface:

$$\Rightarrow \phi = \phi_c$$
 ,  $\theta = 90^\circ$ 

$$\therefore n_1 \sin \phi_c = n_2 \sin 90^\circ$$

$$\therefore n_1 \sin \phi_c = n_2$$

### If the rarer medium is

Air 
$$(n_2 = n_{air} = 1)$$

Not air

So.

$$n_1 = n$$
 ,  $n \sin \phi_c = 1$ 

$$n_1 \sin \phi_c = n_2$$

$$\sin \phi_c = \frac{1}{n} = \frac{v}{c} = \frac{\lambda_1}{\lambda_2}$$

$$\sin \phi_c = \frac{\mathbf{n}_2}{\mathbf{n}_1} = \frac{\mathbf{v}_1}{\mathbf{v}_2} = \frac{\lambda_1}{\lambda_2} = {}_{\mathrm{I}}\mathbf{n}_2 = \frac{\sin (\phi_c)_1}{\sin (\phi_c)_2}$$

### Where

- (n) is the absolute refractive index of the denser medium (n > 1).
- $(\phi_c)$  is the critical angle of the medium with air.
- $n_1 > n_2$
- $\phi_c$  is the critical angle between the two media.
- (φ<sub>c</sub>)<sub>1</sub> is the critical angle of the first medium with air.
- (φ<sub>c</sub>)<sub>2</sub> is the critical angle of the second medium with air.

# Note:

• Knowing that  $\sin \phi_c$  is always between 0 and 1 (0 <  $\sin \phi_c$  < 1), so when calculating the critical angle between two media, the value of the quantity in the numerator must be always less than the value of the quantity in the denominator.

The factors on which the critical angle between two media depends:

1 The types of material of the two media

2 The wavelength of the incident light ray

Illustration

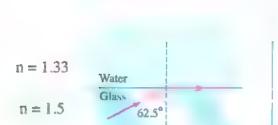

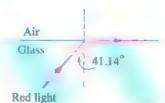

$$n = 1$$
Air
Water

Air

Water

Light ray

### Inample

If the absolute refractive indices of glass and water for a given monochromatic light ray are 1.6 and 1.33 respectively, calculate:

- (a) The critical angle for each of them with air.
- th. The critical angle for the incident light ray that travels from glass to water.

### Solution

$$n_g = 1.6$$
  $n_w = 1.33$ 

The critical angle between glass and air:  $\sin (\phi_c)_g = \frac{1}{n_g} = \frac{1}{1.6}$  $(\phi_c)_g = 38.68^\circ$ 

The critical angle between water and air:  $\sin (\phi_c) = \frac{1}{n_w} = \frac{1}{1.33}$ 

$$(\phi_c)_w = 48.75^\circ$$

(b) 
$$n_g \sin \phi_c = n_w \sin 90$$
  
 $\sin \phi_c = \frac{n_w}{n_g} = \frac{1.33}{1.6}$ 

$$\phi_c = 56.23^\circ$$

the used light in this example is replaced by another monochromatic light of shorter wavelength, what happens to the critical angles for each of glass and water with air?

### Homple 2

The speeds of propagation of a light wave through two different media (x and y) are  $2 \times 10^8$  m/s and  $2.75 \times 10^8$  m/s respectively.

Calculate the critical angle between the two media.

### Solution

$$v_x = 2 \times 10^8 \text{ m/s}$$
  $v_y = 2.75 \times 10^8 \text{ m/s}$   
 $\sin \phi_c = \frac{n_y}{n_x} = \frac{v_x}{v_y} = \frac{2 \times 10^8}{2.75 \times 10^8}$ 

Q Clue

Light travely with the lowest speed through the medium of the highest refractive index.

you are asked to calculate the ratio between the critical angles of light for each

if of the two media with air  $\frac{(\Phi_c)_x}{(\Phi_c)_x}$ , what will be your answer?

### Hample 3

3 piece of dram and was placed at the bottom of a wide basin filled with water for a height of I m, calcutate the smallest diameter of a cork disk that while floating on the water surface will be enough to block the reflected light by the diamond from emerging out of the water surface. Giving that The absolute refractive index of the water.

### Solution

$$h = 1 \text{ m}$$
  $n_{xx} = 1.33$  21

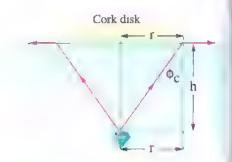

The smallest disk that can block the reflected light from the diamond has to be put on the water surface in such away that its center is directly above the diamond piece and the angle of incidence of the light rays which reach the edge of the disk is equal to the critical angle.

$$\sin \phi_c = \frac{1}{n_w} = \frac{1}{1.33}$$
,  $\therefore \phi_c = 48.75^\circ$ 

: 
$$\tan 48.75 = \frac{r}{h} = \frac{r}{1}$$
 , :  $r = 1.14 \text{ m}$ 

$$\therefore$$
 The diameter of the disk = 2 r = 2.28 m

the height of water in the basin gets increased, what happens to the required diameter for the cork disk that has to float on the surface of water to block out the reflected light from the piece of diamond?

### Example 4

The opposite figure shows a light ray falling on a transparent slab at point x and emerging tangent to the other face at point v. Calculate the refractive index of the transparent slab. (Giving that:  $\sin (90 - \theta) = \cos \theta$ )

$$\phi_1 = 60^\circ$$
  $\theta_2 = 90^\circ$   $n = ?$ 

At point (x):

$$\therefore n = \frac{\sin \phi}{\sin \theta}$$

$$\therefore n = \frac{\sin 60}{\sin \theta_1}$$

1

From the figure, we find:

$$\phi_c = 90 - \theta_1$$

$$\therefore \mathbf{n} = \frac{1}{\sin \phi_c} = \frac{1}{\sin (90 - \theta_1)} = \frac{1}{\cos \theta_1}$$

2

From (1) and (2):

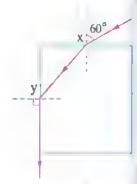

$$\frac{\sin 60}{\sin \theta_1} = \frac{1}{\cos \theta_1}$$

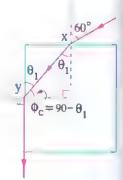

$$\frac{\sin \theta_1}{\cos \theta_1} = \tan \theta_1 = \sin 60$$

$$\theta_1 = 40.89^{\circ}$$

By substituting in equation (2):

$$n = \frac{\sin 60}{\sin 40.89} = 1.32$$

### Example 5

The opposite figure shows the path of a light ray through three media k, f and m that have retractive indices n<sub>k</sub>, n<sub>1</sub> and n<sub>m</sub> respectively, so ......

(a) 
$$n_{\ell} > n_{k} > n_{m}$$

(a) 
$$n_{\ell} > n_{k} > n_{m}$$
 (b)  $n_{k} > n_{\ell} > n_{m}$ 

$$(c)$$
  $n_m > n_k > n_\ell$ 

(c) 
$$n_m > n_k > n_\ell$$
 (d)  $n_\ell > n_m > n_k$ 

### Solution

- The incident light ray on the boundary surface between the two media k and l gets refracted towards the normal.
- $\therefore \Pi_{i} > \Pi_{\nu}$
- The incident light ray on the boundary surface between the two media l and m gets refracted tangent to the surface.
- $\therefore n_i > n_m$
- Applying Snell's law at the boundary surface between the two media k and  $\ell$ :

$$n_k \sin \phi = n_j \sin \theta$$

- Applying Snell's law at the boundary surface between the two media  $\ell$  and m :

$$n_l \sin \theta = n_m \sin 90 = n_m$$

From the two equations (1) and (2):

$$\therefore n_k \sin \phi = n_m$$

$$\therefore n_k > n_m$$

.. The correct choice is (a).

the light ray passes directly from medium k to medium m and falls with the same angle of incidence (φ), what happens to the path of the light ray in medium m?

# Test yourself

A light ray fell from glass on the boundary surface with water, so its wavelength changed from 5000 Å to 5625 Å, calculate the critical angle from glass to water

If the critical angle of glass with air is 41.81° and the critical angle of oil with air is 43.23°, calculate the critical angle of glass with oil.

Choose the correct answer:

In the opposite figure, which angle is representing the critical angle?

- (a Angle (1)
- c Angle (3)

- b Angle (2)
- d Angle (4)

### Applications of the total internal seffection of light

**Optical fibers (fiberoptics)** 

Reflecting prism

Mirage

Optical fibers (fiberoptics)

⊙ Structure:

It is a thread-like tube of a transparent elastic material, which has a relatively high refractive index.

- Oldea of working: Total internal reflection.
  - ⊕ Explaining the idea of working:

When a light ray falls on the internal surface of the optical fiber with an angle of incidence greater than the critical angle,

8

The light ray undergoes multiple successive total internal reflections till it emerges from the other end without any noticeable loss in the light intensity despite of bending this fiber.

Light source

#### O Uses:

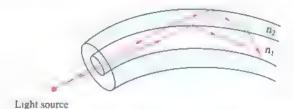

- 1. Transferring light to parts which are hard to reach.
- 2 Transmitting light in non-straight paths without much losses in the light intensity.
- 3 They are widely used nowadays in medical examination devices such as medical endoscopes, which are used in:
  - Diagnosis.
  - Operative surgery using laser beam.
- 4 Communication as light can carry signals of data in optical fiber cables.

 Optical fiber that are made of two layers are preferred to the optical fibers that are made of only one layer;

Because the refractive index of the material of the external layer (n<sub>2</sub>) is less than that of the internal layer (n<sub>1</sub>).

Hence, the external layer reflects any part of light that may escape from the internal layer by total internal reflection so that light is kept travelling inside the fiber.

Accordingly, the intensity of the transmitted light by the optical fiber can be kept constant, which increases the efficiency of light transferring.

### Reflecting prism

#### © Structure:

A triangular glass prism whose angles are 45°, 45° and 90° that is made of glass of refractive index 1.5

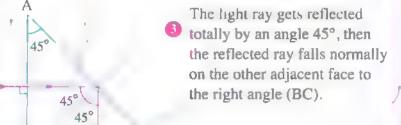

i.e. its critical angle with air is  $41.8^{\circ}$  ( $\approx 42^{\circ}$ ). • Idea of working: Total internal reflection.

### ⊙ Usage:

### 1 Changing the path of the light ray by 90°

- When a light ray is incident normally on one of the adjacent faces to the right angle of the prism (AB for instance).
- The ray passes straight and falls on the face (AC) opposite the right angle by an angle of incidence 45°, i.e., with an angle that is greater than the critical angle of glass.

The ray emerges straight from face BC with an angle of refraction that equals zero.

### 2 Changing the path of the light ray by 180°

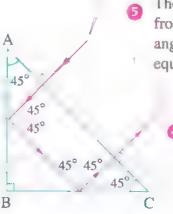

В

- The ray passes straight to fall on one of the adjacent faces to the right angle (AB for instance) by an angle of 45°, i.e., with an angle greater than the critical angle for glass.
- When a light ray is incident normally on the face (AC) opposite the right angle.

The light ray gets reflected

totally by an angle of 45°

to fall on the other adjacent
face (BC) to the right angle
with an angle of 45°.

The ray emerges straight from face AC with an angle of refraction that equals zero.

The ray gets reflected totally for the second time and falls normally on the face (AC) opposite the right angle.

### From the previous, we can compare the two uses of reflecting prism as follows:

The prism's	To change the path of the light ray by 90°	To change the path of the light ray by 180°	
face on which the light ray falls	One of the right-angled faces (face AB)	The face opposite the right angle (hypotenuse AC)	
The angle of incidence (\$\phi\$)	Zero	Zero	
The deviation angle of light	90°	180°	
The angle of ray emergence	Zero	Zero	
The prism's face from which the light ray emerges	The other face of the right-angled faces (face BC)	The same face of light entrance (hypotenuse AC)	
The number of total internal reflections inside the prism	One time	Two times	
An optical instrument that uses the prism			
	Periscope	Binocular	

# Notes:

- Reflecting prisms are preferred to metallic reflecting surfaces or mirrors in some optical instruments for the following reasons:
  - 1 Because they reflect light totally while there is no other reflecting surface of efficiency 100%.
  - 2 In addition, a metallic surface eventually loses its luster, hence its reflection efficiency decreases, this does not happen in a prism.

- (2) The faces of a reflecting prism are coated with non reflective layer of a material like cryolite (aluminum fluoride and magnesium fluoride) whose refractive index is less than that of glass.
  - the critical angle between glass and cryolite becomes small to avoid any reflection losses on the faces of the prism and increase its efficiency.

### Mirage

### • Mirage is a common phenomenon at the noon times during the very hot days, for example:

- Car drivers see the roads as if they are covered with water.
- 2. Hills and palms appear as inverted images such as the image formed due to reflection on water surface. So, the observer thinks that there is water and this phenomenon is known as mirage.

### © Explanation of mirage phenomenon:

- In extremely hot days, the temperature of air layers adjacent to the Earth's surface increases so that their density decreases more than the upper layers. Accordingly the refractive index of the upper layers (n<sub>1</sub>) become larger than that of the lower layers (n<sub>2</sub>).
- When a light ray that is coming from an object passes from the upper air layers (optically denser layers) to the lower air layers (optically rarer layers);
  - 1 It refracts away from the normal according to Snell's law, where :  $n_1 \sin \phi = n_2 \sin \theta$
  - (2) The deviation of the light ray increases as it passes through air layers taking a curved path.
  - (3) When the angle of incidence of the light ray in one layer becomes greater than the critical angle with the following layer, the light ray gets reflected totally till reaching the observer's eye, hence the eye sees the image (the tree) inverted on the extension of the light rays that reach the eye as if it is reflected on water, so the observer thinks that there is water on the ground.

- The opposite figure shows a light ray falling from medium A of refractive index n on the boundary surface with air, hence that light ray can not pass by point ...............
  - (a) x
  - (b) y
  - (C) Z
  - (d)k

- **Explain the following statements:** 
  - 1) Despite the falling of a light ray from an optically denser medium to an optically rarer medium, it doesn't undergo total internal reflection.
  - (2) Part of the light emitted from a source beneath the surface of water might not be seen in air.
  - (3) Optical fibers are used in medical endoscopes.
  - 4) Prisms are preferred to mirrors as reflectors in some optical instruments.
  - (5) The appearing of mirage in hot deserts.
- Four light rays are emitted from a light source under the surface of a liquid of refractive index  $\sqrt{2}$ . If the first ray falls perpendicularly on the surface of the liquid, the second falls at an angle of incidence 30°, the third at 45° and the fourth at 60°, describe what happens for each ray.
- The opposite figure shows a light source at the bottom of a water container.
  - (a) Why doesn't light emerge from regions (a) and (b)?
  - (b) Calculate the value of the angle  $\theta$ . (Where: The refractive index of water = 1.33)

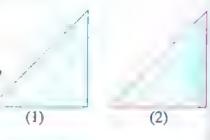

An optical fiber is coated by a thin film whose refractive index is less than that of the fiber's core. If a light beam passes through it as shown in the figure, explain why:

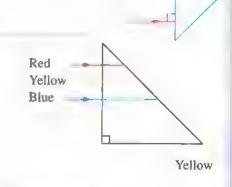

- (a) the direction of the beam does not change at each of S and P.
- (b) there is total reflection at each of Q and R.
- (c) the double layer in the optical fiber is preferred to that of a single layer.
- 5 The opposite figure shows two reflecting prisms where prism (2) is coated with a transparent thin film of another material.
  - (4) What could be the type of the material of the thin film?
  - (b) Which of the two prisms is more efficient?

    And why?

- The opposite figure represents two reflecting prisms. If a light ray falls perpendicular on a face of one of them, trace the path of the light ray till it emerges from the other prism.
- The opposite figure shows a right angle isosceles triangular prism where three different colors of light rays fall on one of the adjacent faces to the right angle. So, if the yellow ray emerges tangent to the opposite face of the right angle, trace the path of the other red and blue rays, with explanation.

The opposite figure shows a light lamp which is placed at the bottom of a container under two layers of different liquids (1), (2). The refractive index of the lower layer is 2 while the refractive index of the upper one is 1.5. A light ray falls from the lamp on the boundary between the two liquids at an angle of incidence 35°.

Trace the light ray and show if the ray will emerge to the air or not.

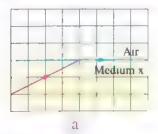

## the Lions that me was high levels of thirdship

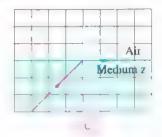

### Choose the correct answer:

Three transparent materials have absolute refractive indices  $n_x$ ,  $n_y$  and  $n_z$ , a light ray is incident on the interface of each of them with air as represented in the following figures,

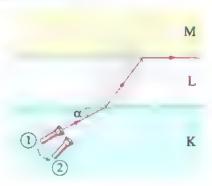

so, the speed of light ......

- is higher in medium x
- is higher in medium z

- b is higher in medium y
- d is the same in all of them
- A light ray is incident on a square glass slab as in the figure, then the refractive index of the glass that makes the ray emerges tangent to the vertical face (xy) of the slab equals ............ (Where:  $\sin (90^{\circ} - \theta) = \cos \theta$ )

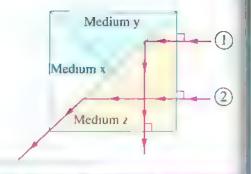

Three layers of transparent materials (M, L, K) through which a light ray passes from material K towards material M as shown in the opposite figure, if the light source is moved from position (1) to position (2) such that the angle a gets increased, the light ray when it falls on the boundary surface between material L and material M will ......

- (a) be refracted towards the normal
- b be refracted away from the normal
- (c) be refracted tangent to the boundary surface
- d undergoes total internal reflection

- The opposite figure shows the paths of two light rays, so what is the correct order for the absolute refractive indices of the three media x, y and z?
- (b)  $n_v < n_x < n_z$
- $(c) n_z < n_x < n_v$   $(d) n_x < n_v < n_z$

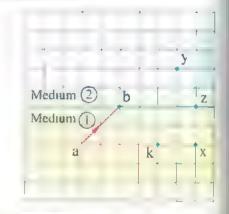

Medium (2)

Medium (3)

- The opposite figure shows three transparent media (1), (2) and (3), so if a light ray passes as shown in the figure, what will be the correct order of light speeds through these three media?
  - (a)  $v_1 > v_2 > v_3$
- (b)  $v_1 > v_3 > v_2$

Medium (1)

- $(c) V_2 > V_3 > V_1$
- (d)  $V_3 > V_2 > V_1$
- A light ray ab is incident from medium 1 whose refractive index is n towards medium (2) whose refractive index is less than n as represented by the drawing scale shown in the figure, so if the critical angle between these two media is 26°, the light ray will pass from point b to point ....

(a) x

(c) z

- (d) k
- A light ray falls from glass on the boundary surface with air at an angle of incidence that equals the critical angle, so it gets refracted tangent to the glass surface. If a layer of water is placed on the glass surface, then the angle of emergence of the ray to air equals .... . .... (Given that: the refractive index of glass = 1.5, the refractive index of water =  $\frac{4}{3}$ ) (a) 42° (b) 48° © 62°

## Answer the following questions:

[] Three light sources were placed away from each other at the bottom of water basin the first source gives yellow light, the second gives red light and the third gives blue light. When the three sources are switched on, three circular light spots of different areas have appeared on the surface of water. Arrange the sources ascendingly according to the area of the spot circle and explain why each light source has different spot circle area.

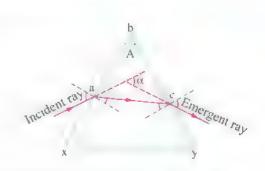

### Triangular prism:

It is a piece of a solid transparent material (like glass) with two identical faces in the shape of a triangle connected by three lateral rectangular faces.

## When a light ray falls from air on face xb of the shown triangular prism;

- It gets refracted inside the prism taking the path ac.
- So, it falls on face yb and if its angle of incidence on face yb is less than the critical angle between the material of the prism and the air, it gets refracted and emerges from the face yb of the prism.

i.e The light ray gets deviated from its path due to passing through the prism by a certain angle called the angle of deviation  $(\alpha)$ , which can be defined as follows:

## The angle of deviation ( $\alpha$ ): ......

It is the acute angle between the extensions of the incident light ray and the emergent light ray.

## Poducing the lave of a triangular prime

In the triangular prism shown in the opposite figure:

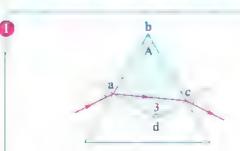

is the apex angle of the prism (the angle between the two faces of the prism where the light ray enters through one of them and emerges from the other one)

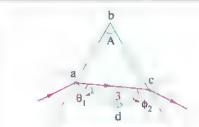

- φ, is the first angle of incidence (where light enters)
- $\theta_1$  is the first angle of refraction
- $\Phi_2$  ) is the second angle of incidence (inside the prism)
- $\left(\theta_{2}\right)$  is the angle of emergence
  - $\alpha$  ) is the angle of deviation

## Hence, we can deduce each of:

First The apex angle of the prism (A)

- $\therefore \overline{ad} \perp \overline{ab}, \overline{dc} \perp \overline{cb}$
- i.e.  $\angle$  bad = 90°,  $\angle$  bcd = 90°
- ∴ ∠ bad + ∠ bcd = 180°
- .. Shape abod is cyclic quadrilateral.
- .. The sum of each two opposite angles = 180°
- $\therefore A + \hat{3} = 180^{\circ}$

In the triangle acd:

- ∴ The sum of angles = 180°
- $\therefore \theta_1 + \phi_2 + \hat{3} = 180^{\circ}$

From 1 and 2

$$\therefore A + \hat{3} = \theta_1 + \phi_2 + \hat{3}$$

$$\therefore A = \theta_1 + \phi_2$$

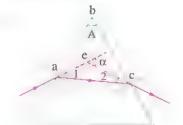

## **Second** The angle of deviation (α)

$$: \phi_1 = \hat{1} + \theta_1 , \theta_2 = \hat{2} + \phi_2$$

(since they are vertically opposite angles)

$$\hat{1} = \phi_1 - \theta_1 \quad , \quad \hat{2} = \theta_2 - \phi_2$$

: The angle of deviation is an exterior angle of the triangle aec.

$$\therefore \alpha = \hat{1} + \hat{2}$$

From (1) and (2)

$$\therefore \alpha = \phi_1 - \theta_1 + \theta_2 - \phi_2 = \phi_1 + \theta_2 - (\theta_1 + \phi_2)$$

$$\therefore A = \theta_1 + \phi_2 \qquad \qquad \therefore | \alpha = \phi_1 + \theta_2 - A$$

## The refractive index of the material of the prism (n)

• When a light ray passes from a medium to a prism such that if the medium is:

Air

$$n_{prism} = \frac{\sin \phi_{1 \text{ (air)}}}{\sin \theta_{1 \text{ (prism)}}}$$
$$= \frac{\sin \theta_{2 \text{ (air)}}}{\sin \phi_{2 \text{ (prism)}}}$$

Other medium, not air

 $\frac{n_{\text{prism}}}{n_{\text{medium}}} = \frac{n_{\text{prism}}}{n_{\text{medium}}} = \frac{\sin \phi_{1 \text{ (medium)}}}{\sin \theta_{1 \text{ (prism)}}}$   $= \frac{\sin \theta_{2 \text{ (medium)}}}{\sin \phi_{2 \text{ (prism)}}}$ 

# If the triangular prism is surrounded by air, then the factors that affect each of:

## The angle of refraction $(\theta_j)$

The second angle of incidence (\$\phi\_2)

The angle of emergence  $(\theta_*)$ 

The angle of deviation (α)

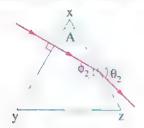

- 1 The refractive index of the prism for the used light (n).
- ② The first angle of incidence  $(\phi_1)$ .
- ① The refractive index of the prism for the used light (n).
- 2 The first angle of incidence (\$\phi\_1).
- The apex angle (A).

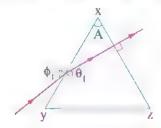

## Special cases for the triangular prism

- When the light ray falls normal on the face of the prism
- 2 When the light ray emerges normal from the face of the prism

The ray

enters through face xy without any refraction emerges from face xz without any refraction

Such that

 $\phi_1 = \theta_1 = 0^\circ$  (the minimum value for the first angle of incidence)

 $\phi_2 = \theta_2 = 0^{\circ}$  (the minimum value for the angle of emergence)

So that

 $\phi_2 = A$  (the maximum value for the second angle of incidence)

 $\theta_1$  = A (the maximum value for the second angle of refraction)

At the emergence of the ray from face xz

$$\alpha = \theta_2 - A$$

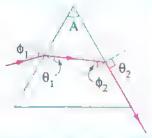

$$\alpha = \phi_1 - A$$

(8) When the second angle of incidence  $(\phi_2)$  equals the critical angle of the prism:

In this case  $\phi_1$  is the minimum angle of incidence on the face of the prism that makes the ray emerge from the opposite face.

$$\phi_2 = \phi_c$$
,  $\theta_2 = 90^\circ$ 

$$\therefore \mathbf{n} = \frac{1}{\sin \phi_2}, \mathbf{A} = \theta_1 + \phi_c$$

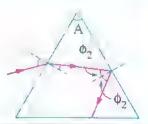

When the second angle of incidence (inside the prism) is greater than the critical angle of the prism:

The ray encounters total internal reflection where:

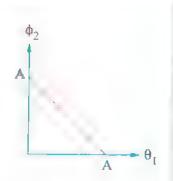

The angle of reflection = The second angle of incidence

And the ray falls on the third face of the prism.

## Notes:

- (1) The graph of the second angle of incidence  $(\phi_2)$  versus the angle of refraction  $(\theta_1)$  can be represented as shown in the opposite figure, where:  $\phi_2 = A - \theta_1$
- (2) When a light ray is incident with an angle  $(\phi_1)$  on one of the faces of a triangular prism such that the second angle of incidence  $(\phi_2)$  is less than the critical angle  $(\phi_c)$ , the ray emerges from the opposite face with an angle of emergence  $(\theta_2)$  and when increasing the first angle of incidence  $(\phi_1)$ :

The first angle of refraction  $(\theta_1)$ increases since

The second angle of incidence  $(\phi_2)$  $A = \phi_2 + \theta_1$ decreases since

The angle of emergence  $(\theta_2)$ decreases since

## listical of sulving the problems of mlargals; (

When a light ray falls on one of the lateral faces of a triangular prism, we use Snell's law:

$$n_1 \sin \phi_1 = n_2 \sin \theta_1$$

Where:  $n_1$  is the refractive index of the surrounding medium,  $n_2$  is the refractive index of the prism.

When the light ray passes inside the prism and falls on the opposite face, we use the relation.

$$\mathbf{A} = \boldsymbol{\theta}_1 + \boldsymbol{\phi}_2$$

From the geometry of the figure, we calculate the angle of incidence of the light ray on the internal surface of the prism and compare it with the critical angle of the prism with its surrounding medium to determine the path of the light ray at that surface, so if the second angle of incidence (inside the prism):

### is less than

the critical angle between the material of the prism and the surrounding medium  $(\phi_2 < \phi_c)$ 

## equals

the critical angle between the material of the prism and the surrounding medium  $(\phi_2 = \phi_c)$ 

## Hence, the light ray

gets refracted away from the gets refracted tangent to normal line on the face of the the face of the prism so prism, so we apply Snell's law: that:

$$\theta_2 = 90^{\circ}$$

## is greater than

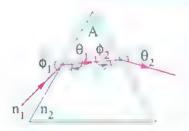

the critical angle between the material of the prism and the surrounding medium

$$(\phi_2 > \phi_c)$$

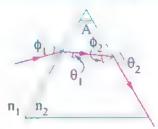

undergoes total internal reflection inside the prism so that:

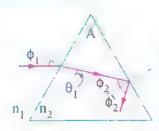

The angle of reflection =  $\phi_1$ 

## And this can be represented by the following diagram.

 $n_2 \sin \phi_2 = n_1 \sin \theta_2$ 

## Example II

The opposite figure shows a light ray being incident normally on one of the faces of a triangular prism of in apex angle 40., if  $\theta_s = 1.5 \ \phi_s$ , the refractive index of the prism equals

(b) 1.35

(c) 1.51

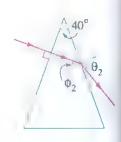

d 1.72

## Solution

$$\theta_2 = 1.5 \, \phi_2$$

$$A = 40^{\circ}$$
  $\theta_2 = 1.5 \, \phi_2$   $\theta_1 = \phi_1 = 0^{\circ}$ 

$$n = 0$$

$$\therefore A = \theta_1 + \phi_2$$

$$\theta_1 = 0^{\circ}$$

$$\therefore \phi_2 = A \approx 40^\circ$$

$$\therefore \ \phi_2 = A = 40^{\circ} \qquad \qquad \therefore \ \theta_2 = 1.5 \times 40 = 60^{\circ}$$

• Applying Snell's law:  $n \sin \phi_2 = \sin \theta_2$ 

$$n = \frac{\sin \theta_2}{\sin \phi_2} = \frac{\sin 60}{\sin 40} = 1.35$$

- ... The correct choice is (b).
- the angle of incidence of the light ray is changed to make the ray emerges normally, what will be the new angle of incidence on the prism  $(\phi_1)$ ?

## Example 2

The opposite figure represents a light ray that is in idential an imple of 45 on one of the faces of an equitateral triangular prism whose refractive index equals 1.5, so:

- ... The angle at which the ray emerges from the prism equals ..........
  - a) 28.13°
- (b) 31.87°
- (c 42.12°
- (d 52.37°
- (ii) The angle of deviation for the light ray equals ......
- (a) 37.37°
- (b. 41.43°
- © 52.63°
- (d 67.37°

## Solution

$$\phi_1 = 45^{\circ}$$
  $A = 60^{\circ}$   $n = 1.5$   $\theta_2 = ?$ 

? 
$$\alpha = 2$$

## **Q** Clue

To find the angle of emergence  $(\theta_{\gamma})$ , we must calculate  $\theta_1$  then  $\phi_2$ 

Applying Snell's law:

$$\sin \phi_1 = n \sin \theta_1$$

$$\sin \theta_1 = \frac{\sin 45}{1.5}$$

$$\theta_1 = 28.13^{\circ}$$

$$A = \theta_1 + \phi_2$$

$$\phi_2 = A - \theta_1 = 60 - 28.13 = 31.87^\circ$$

$$\because \sin \phi_{\rm e} = \frac{1}{n} = \frac{1}{1.5}$$

$$\therefore \phi_c = 41.81^\circ$$

By comparing the second angle of incidence  $(\phi_2)$  with the critical angle of the prism's material, we find:

$$\phi_2 < \phi_c$$

.. The ray passes from the face of the prism so that Snell's law can be applied:

$$\sin \theta_2 = n \sin \phi_2 = 1.5 \sin 31.87^\circ$$

$$\therefore \theta_2 = 52.37^{\circ}$$

.. The correct choice is (d).

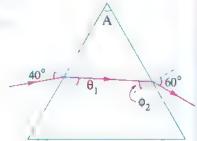

(ii) 
$$\alpha = \phi_1 + \theta_2 + A$$
  
=  $45 + 52.37 - 60 = 37.37^\circ$ 

- .. The correct choice is (a).
- we need to make the light ray undergo a total internal reflection inside the prism, what change should be done to the angle of incidence to do that?

## Example 3

The opposite figure represents the path of a light ray through a triangular prism, hence the angle of refraction  $\theta_i$  is

- $\cdot$  greater than the second angle of incidence  $(\phi_2)$
- (b) less than the second angle of incidence (φ<sub>2</sub>)
- c equal to the second angle of incidence (φ<sub>2</sub>)
- (d) equal to the apex angle of the prism (A)

## Solution

$$\therefore n = \frac{\sin \phi_1}{\sin \theta_1} = \frac{\sin \theta_2}{\sin \phi_2}$$

$$\therefore \frac{\sin 40}{\sin \theta_1} = \frac{\sin 60}{\sin \phi_2}$$

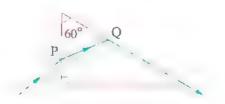

$$\therefore \sin \theta_1 < \sin \phi_2$$

$$\theta_1 < \phi_2$$

What the angle of incidence  $(\phi_1)$  of the light ray on the prism gets increased, what will happen to the angle of emergence of the light ray?

## Example 4

In the opposite figure, a blue light ray falls on the face of a prism at point P so that the angle of refraction equals 23° then it falls on the opposite face at point Q and emerges tangent to that face, hence:

- (1) The critical angle of the prism's material for the blue light equals
- (b. 37°
- C 42°
- (d) 60°
- m The refractive index of the prism's material for the blue light equals
  - (a) 1.15
- (b) 1.41
- (c) 1.66
- (d, 1.72)

## Solution

$$\theta_1 = 23^{\circ}$$
  $A = 60^{\circ}$   $\theta_2 = 90^{\circ}$   $\phi_1 = ?$   $n = ?$ 

$$(i) A = \theta_1 + \phi_2$$

(i) 
$$A = \theta_1 + \phi_2$$
 ,  $\therefore 60 = 23 + \phi_2$  ,  $\therefore \phi_2 = 37^\circ$ 

$$\therefore \phi_2 = 37^\circ$$

.. The ray has emerged tangent.

$$\therefore \phi_c = \phi_2 = 37^{\circ}$$

... The correct choice is (b.

(ii) 
$$n = \frac{1}{\sin \phi_0} = \frac{1}{\sin 37} = 1.66$$

... The correct choice is (c),

the blue light ray is replaced by a red light ray that falls at the same angle on the prism, will the light ray undergo total internal reflection at the face of the prism opposite the right angle?

## Example 5

In the opposite figure, if the refractive index of the prism's material is 1.5:

- (a) Trace the light ray inside the prism.
- (b) Find the angle of emergence from the prism.
- (c) Find the angle of deviation.

## Solution

$$n = 1.5$$
  $\theta_2 = ?$   $\alpha = ?$ 

(a) Applying Snell's law:  $\sin \phi_1 = n \sin \theta_1$ 

$$\sin \theta_1 = \frac{\sin \phi_1}{n} = \frac{\sin 60}{1.5}$$

$$\theta_1 = 35.26^{\circ}$$

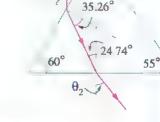

$$\theta_1 = 35.26^{\circ}$$
 ,  $A = \theta_1 + \phi_2$ 

$$60 = 35.26 + \phi_2$$
 ,  $\phi_2 = 24.74^\circ$ 

$$\phi_2 = 24.74$$

(b) 
$$\sin \phi_c = \frac{1}{n} = \frac{1}{1.5}$$
 ,  $\phi_c = 41.81^\circ$ 

$$\phi_c = 41.81^\circ$$

By comparing the second angle of incidence  $(\phi_2)$  with the critical angle for the prism ( $\phi_c = 41.81^\circ$ ), we find:  $\phi_2 < \phi_c$ 

• Applying Snell's law:

$$\sin \theta_2 = n \sin \phi_2 = 1.5 \times \sin 24.74$$

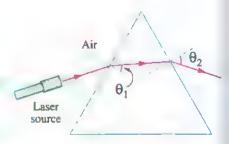

$$\theta_{3} = 38.88^{\circ}$$

$$(c) \propto = (\phi_1 + \theta_2) - A$$

$$=60 + 38.88 - 60 = 38.88^{\circ}$$

## Example 6

A triangular prism of material's refractive index 1.5 is placed at the bottom inside an empty sink where a laser ray is incident on it and emerges as shown in the opposite figure. If water of refractive index 1.33 is poured into the sink fill it has covered the prism, what happens to the angle of refraction  $(\theta_i)$  and that of emergence  $(\theta_i)$ ?

## Solution

When the prism is surrounded by air:

$$\sin \phi_1 = n_{\text{prism}} \sin \theta_1$$

When the prism is surrounded by water:

$$n_{\text{water}} \sin \phi_1 = n_{\text{prism}} \sin \hat{\theta}_1$$

Dividing equation (1) by (2):

$$\frac{1}{n_{\text{water}}} = \frac{\sin \theta_1}{\sin \dot{\theta}_1}$$

$$\therefore \sin \hat{\theta}_1 = n_{\text{water}} \sin \theta_1$$

$$n_{\text{water}} > 1$$

$$\therefore \sin \hat{\theta}_1 > \sin \theta_1$$

 $\therefore \theta_{\tau}$  increases when the prism is surrounded by water.

- $A = \theta_1 + \phi_2$
- :. When  $\theta_1$  increases,  $\phi_2$  decreases, so  $\theta_2$  decreases.

in the first case (before pouring water into the sink), the light source has been changed by another of higher frequency, what will be the effect of this change on the angle of emergence of the light ray from the prism?

# Test yourself -

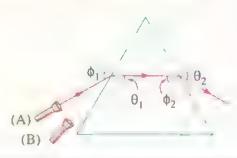

### Choose the correct answer:

- (1) A light ray is incident with an angle of incidence on one of the lateral faces of a triangular prism whose material refractive index is n, hence it deviates by an angle a, so if the prism is immersed in a liquid of refractive index 0.8 n and a light ray gets incident on it with the same angle  $\phi_1$ , the deviation angle of the light ray ......
  - a decreases
- b increases
- vanishes
- d doesn't change

- (2) In the opposite figure, if the light source is moved from position (A) to position (B), the angle of emergence  $(\theta_2)$  ..............
  - a) decreases
- (b) increases
- (c) vanishes
- d doesn't change

# Tracing the path of a light ray through a triangular prism and confirming the laws of the prism.

### ools:

- An equilateral glass triangular prism (of apex angle 60°).
- A protractor.

- A ruler.

- Pins.

### teps:

- Place the glass prism on a drawing paper sheet and mark its position with a fine pencil line.
- 2. Draw a line ab inclined to one of the faces of the prism to represent the incident ray.
- 3. Place two pins (1, 2) on the line ab.
- 4. Look at the other side of the prism to see the image of the two pins, one behind the other.
- 5. Place two other pins (3) and (4) exactly in front of pins (1) and (2) such that the four pins appear to be in one straight line.
- 6 Draw a straight line cd between the two pins (3) and (4) to represent the emergent ray.
- 7 Remove the prism and the pins and join b and c to locate the path of the ray (abcd) from air to glass to air again.
- 8. Extend cd to meet the extension of ab. The acute angle between them is the angle of deviation  $(\alpha)$ .
- 9. Measure:  $\phi_1$ ,  $\theta_1$ ,  $\phi_2$ ,  $\theta_2$  and  $\alpha$  using the protractor.
- 10. Record the results in a table as the following:

1 <sup>st</sup> angle of incidence (\$\phi_1\$)	Angle of refraction $(\theta_j)$	$2^{nd}$ angle of incidence $(\phi_2)$	Angle of emergence $(\theta_2)$	Angle of deviation (α)	Apex angle (A)

11. Compare the results with the calculated values from the relations:

$$A = \theta_1 + \phi_2$$
,  $\alpha = (\phi_1 + \theta_2) - A$ 

## **Deviation of Light in** a Triangular Prism

## Multiple choice questions

The opposite figure represents the path of a light ray through a triangular prism, what is the mathematical expression that relates correctly

angle x with the other shown angles in the figure?

$$(b) x = a - b$$

$$\bigcirc x = b - c$$

$$(\mathbf{d}) \mathbf{x} = \mathbf{b} + \mathbf{c}$$

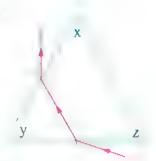

In the opposite figure, which angle represents the apex angle of the prism when calculating the deviation angle of the light ray?

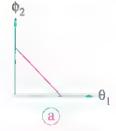

b Angle y

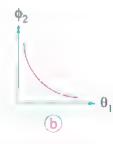

C Angle z

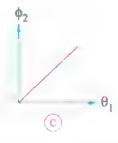

d. The three angles

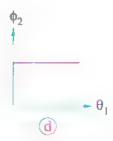

Which of the following graphs represents the relation of the second angle of incidence  $(\phi_i)$ versus the angle of refraction  $(\theta_i)$  for a light ray that gets incident on the face of a triangular prism with different angles of incidence?

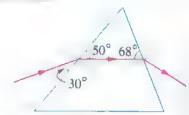

- The following three physical quantities are related to the deviation of light in a triangular prism:
  - (I) The apex angle of the prism
  - (II) The refractive index of the prism's material for the used light
  - (III) The angle of deviation

So, on which of these quantities does the second angle of incidence in the triangular prism depend?

- (a) (I), (II)
- (l), (III)
- © (II), (III)
- (d) (l), (II), (III)

- c) 42,42°
- d 46.46°
- In the opposite figure, if the red laser source is required to be changed with a blue laser source, yet the light ray is still wanted to emerge tangent to the face of the prism, what should be done to the angle of incidence  $\phi$ ,?

- (a) It should be increased.
- b It should be decreased.
- (c) It shouldn't be changed.
- d The answer is indeterminable.
- The opposite figure represents a triangular prism (xyz) placed on a rotatable disk in which a laser light ray is incident on face xy and emerges tangent to face xz, so when the disk is rotated slightly in the clockwise direction, the laser light ray at face xz will ......

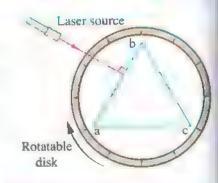

- (a) emerge with an angle smaller than 90°
- b) emerge tangent to face yz
- undergo total internal reflection inside the prism
- d emerge normal to face xz

## The minimum angle of deviation in the triangular priors

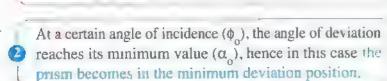

The opposite figure represents the incidence of a light ray perpendicularly on face ab of a triangular prism abc that is placed on a rotatable disk, so if the disk has been rotated to increase the angle of incidence of the light ray (φ<sub>1</sub>), then measuring the angle of emergence from face be multiple times and after that calculating the angle of deviation (α) each time from the relation:

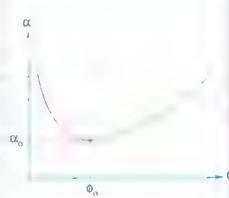

$$\alpha = \phi_1 + \theta_2 - A$$

Then when plotting a graph of deviation angle (c. versus the first angle of incidence  $(\phi_1)$  for the light ray, we find that:

At a small angle of incidence (φ<sub>1</sub>), the angle of deviation (α) will be large and as the first angle of incidence (φ<sub>1</sub>) increases, the angle of deviation (α) decreases.

By increasing the first angle of incidence (φ<sub>1</sub>) above
 its value at the minimum deviation position, the angle of deviation (α) increases again.

## · It was found that at minimum deviation position;

The angle of emergence  $(\theta_2)$  = The first angle of incidence  $(\phi_1)$  =  $\phi_0$ 

The second angle of incidence  $(\phi_2)$  = The angle of refraction  $(\theta_1)$  =  $\theta_0$ 

# deviation position

## When the triangular prism is being in the minimum deviation position, then

$$\phi_1 = \theta_2 = \phi_0$$

$$\alpha = \phi_1 + \theta_2 - A$$

$$\therefore \alpha_0 = 2 \phi_0 - A$$

$$\therefore \phi_0 = \frac{\alpha_0 + A}{2}$$

$$\theta_1 = \phi_2 = \theta_0$$

$$A = \theta_1 + \phi_2$$

$$\therefore A = 2 \theta_0$$

$$\theta_0 = \frac{A}{2}$$

## Applying Snell's law:

$$n_{\text{medium}} \sin \phi_{\text{o}} = n_{\text{prism}} \sin \theta_{\text{o}}$$

## So, if the medium surrounding the prism is:

### Air

$$\therefore n_{prism} = \frac{\sin \phi_o}{\sin \theta_o}$$

$$\therefore n_{\text{prism}} = \frac{\sin\left(\frac{\alpha_o + A}{2}\right)}{\sin\left(\frac{A}{2}\right)}$$

# Another medium other than air

$$\therefore \frac{n_{\text{prism}}}{n_{\text{medium}}} = \frac{\sin \phi_o}{\sin \theta_o}$$

$$\frac{n_{\text{prism}}}{n_{\text{medium}}} = \frac{\sin\left(\frac{\alpha_o + A}{2}\right)}{\sin\left(\frac{A}{2}\right)}$$

the second angle of incidence  $(\phi_2)$  and the angle of refraction  $(\theta_1)$  in a triangular prism:

• The first angle of refraction  $(\theta_1)$  and the second angle of incidence  $(\phi_2)$  are related by the relation:

$$A = \theta_1 + \phi_2$$

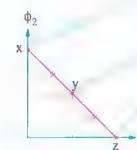

$$\therefore \phi_2 = A - \theta_1$$

de religion bigunges

Since, the apex angle (A) is constant for the same prism, so as  $\theta_1$  increases,  $\phi_2$  decreases and the relation between them  $(\theta_1, \phi_2)$  can be represented as follows:

$$\phi_1 = \theta_1 = 0 \qquad , \qquad \phi_2 = A$$

The light ray falls perpendicular to the face of the prism

$$\phi_1 = \theta_2$$
,  $\theta_1 = \phi_2$ 

The prism is at the minimum deviation position

$$\phi_2 = \theta_2 = 0 \qquad , \qquad \theta_1 = A$$

The light ray emerges perpendicularly from the prism's face

The factors on which the angle of minimum deviation (α) depends in a triangular prism:

The apex angle of the prism (A):

1.	The apex angle of the prism (A)	>	Increases,	The minimum angle of deviation (α <sub>a</sub> )	Increases
11	the prism (A)	)	increases,	_	I

The refractive index of the prism's material for the used light (n)

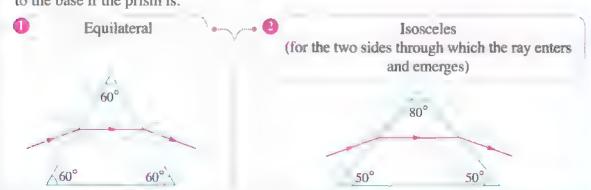

The refractive index of the prism's \ Increases, \ The minimum angle of deviation  $(\alpha_0)$  Increases

 $\bigcirc$  The wavelength of the used light ( $\lambda$ ):

The wavelength of the used light  $(\lambda)$  Decreases, The minimum angle of deviation  $(\alpha_0)$  Increases

Note:

 In the minimum deviation position, the light ray inside the triangular prism will be parallel to the base if the prism is:

# Test yourself

theose the correct a cover

In which of the following cases the prism is in the minimum deviation position?

## Example 1

A triangular prism is made of a material whose refractive index is \\ having an aprix angle that equals 60°, calculate:

(a) The minimum angle of deviation in the prism.

The angle of incidence and the angle of emergence at minimum deviation.

## Solution

$$n = \sqrt{2}$$
  $A = 60^{\circ}$   $\alpha_0 = ?$   $\phi_1 = ?$   $\alpha_2 = ?$ 

(a) 
$$n = \frac{\sin\left(\frac{\alpha_0 + A}{2}\right)}{\sin\left(\frac{A}{2}\right)}$$
,  $\sqrt{2} = \frac{\sin\left(\frac{\alpha_0 + 60}{2}\right)}{\sin\left(\frac{60}{2}\right)}$ 

$$\sin\left(\frac{\alpha_0 + 60}{2}\right) = \frac{\sqrt{2}}{2}$$

$$\frac{\alpha_o + 60}{2} = 45^\circ \qquad \qquad \alpha_o = 30^\circ$$

(b) 
$$\phi_1 = \theta_2 = \phi_0 = \frac{\alpha_0 + A}{2} = \frac{30 + 60}{2} = 45^\circ$$

the light ray falls on the prism with an angle greater than the angle that has been calculated in the example, what happens to the deviation angle of the ray?

## Memple 2

A triangular prism has an operangle of 60. If the vision of some in equal teacher he angle of refrective at the annal number of the experience of the experi

## Salution

$$A = 60^{\circ}$$

$$A = 60^{\circ}$$
  $\phi_0 = 2 \theta_0$   $\alpha_0 = ?$ 

$$\alpha_0 = ?$$

When the triangular prism is in the minimum deviation position:

$$\phi_o = \frac{\alpha_o + A}{2} \quad , \quad \theta_o = \frac{A}{2}$$

$$\phi_o = 2 \theta_o$$

$$\therefore \frac{\alpha_0 + A}{2} = 2\left(\frac{A}{2}\right)$$

$$\therefore \alpha_0 + A = 2 A$$

$$\therefore \alpha_0 = 2 A - A = A = 60^{\circ}$$

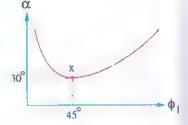

a blue light ray falls on the prism instead of the red ray, what will happen to the value of the angle of minimum deviation through the same prism?

## Example 3

The opposite graph represents the relation between the angle of desiation (C) for a light ray passing through a triangular prism and the first angle of incidence (2) on the face of the prism, calculate:

(c) The angle of emergence from the prism at point x.

## Solution

(a) Point x represents the position of minimum deviation in the prism:

$$\phi_0 = \frac{\alpha_0 + A}{2}$$

$$\therefore \mathbf{A} = 2 \phi_{o} - \alpha_{o}$$
$$= (2 \times 45) - 30$$

$$= 60^{\circ}$$

$$(b) n = \frac{\sin\left(\frac{\alpha_o + A}{2}\right)}{\sin\left(\frac{A}{2}\right)} = \frac{\sin\left(\frac{30 + 60}{2}\right)}{\sin\left(\frac{60}{2}\right)} = \sqrt{2}$$

Another Solution:

$$\theta_0 = \frac{A}{2} = \frac{60}{2} = 30^\circ$$

$$\theta_0 = \frac{A}{2} = \frac{60}{2} = 30^\circ$$
 ,  $n = \frac{\sin \phi_0}{\sin \theta_0} = \frac{\sin 45}{\sin 30} = \sqrt{2}$ 

(c) 
$$\theta_2 = \phi_1 = \phi_0 = 45^\circ$$

## Example 4

The opposite figure represents the path of a light ray through a triangular prism, so the refracte condex of the prism mater alequals . . . .

## Solution

From the figure, we find:

$$\phi_1 = 90 - 30 = 60^\circ$$

$$\theta_2 = 90 - 30 = 60^\circ$$

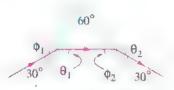

$$\therefore \phi_1 = \theta_2$$

.. The prism is in the minimum deviation position.

$$\theta_1 = \phi_2 = \frac{A}{2} = \frac{60}{2} = 30^{\circ}$$

$$\therefore \alpha = \frac{\sin \phi_t}{\sin \theta_1} = \frac{\sin 60}{\sin 30} = \sqrt{3}$$

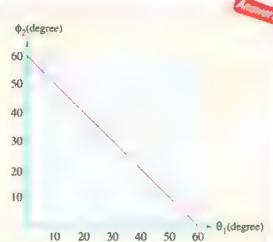

.. The correct choice is (c).

what the prism has a greater apex angle and the incident ray falls with the same angle on its face, what will happen to the deviation angle of the ray?

## Test yourself

The opposite graph depicts the relation between the second angle of incidence (φ<sub>2</sub>) and the angle of refraction (θ<sub>1</sub>) in a triangular prism of refractive index 1.5 Calculate the angle of minimum deviation.

Could a light ray fall on a triangular prism two times with two different angles of incidence and deviate in both times with the same angle of deviation (α)?

## El Choose the correct answer

- (a) 30°
- (b) 45°
- © 60°
- (d) 75°

## Disposition of light by the triumpake prion

Visible (white) light consists of a range of wavelengths that extends nearly from 400 nm to 700 nm, hence if a beam of white light falls on a triangular prism in the minimum deviation position, it emerges from the prism separated into a spectrum of colors that can be assigned to seven colors of spectrum which can be listed as their order from the apex to the base of the prism as follows:

Red Orange Yellow Green Blue Indigo Violet

### Explaining the dispersion of light by a triangular prism:

As the wavelength ( $\lambda$ ) of light m  $\alpha \rightarrow 0$ , the index of refraction (n) which this light encounters at entering the prism d  $\alpha \rightarrow 0$ , hence the angle of deviation ( $\alpha$ ) of a ray of that light through the prism decreases, therefore we find:

Red light has the least angle of deviation because it has the longest wavelength and as  $(n \propto \frac{1}{\lambda})$ , red light encounters the least value of refractive index for the prism and the smallest deviation.

Violet light has the largest angle of deviation because it has the shortest wavelength and hence it has the largest refractive index and the largest deviation.

 The dispersion of light happens distinctly when the prism is set in minimum deviation position.

## This prise

- O It is a triangular prism that is made of a transparent material (like glass) and has a very small apex angle that does not exceed 10° and it is always in the position of minimum deviation.
  - Some concepts related to the thin prism

1 Deviation angle

(2) Angular dispersion 3
Dispersive power

# Deviation angle

# dualing the deviation angle in the thir primi

- The thin prism is always in the position of minimum deviation when it is surrounded by air.
- .: When the thin prism is surrounded by air, the refractive index (n) of its material can be determined from the relation:

$$n = \frac{\sin\left(\frac{\alpha_0 + A}{2}\right)}{\sin\left(\frac{A}{2}\right)}$$

 $\therefore \frac{\alpha_0 + A}{2}$  are small angles, then the sine of these angles is approximately equal to their angles in radians.

$$\therefore n = \frac{\frac{\alpha_o + A}{2}}{\frac{A}{2}} = \frac{\alpha_o + A}{A}$$

Notice that the ratio between the angles in radians equals the ratio between them in degrees.

$$\alpha_0 + A = An$$

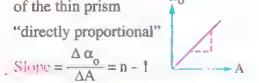

$$\alpha_0 = A(n-1)$$

When the thin prism is put in any other medium other than air, the angle of deviation will be determined from the relation:

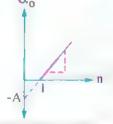

$$\alpha_{o} = A \left( \frac{n_{prism}}{n_{medium}} - 1 \right)$$

#### The factors on whi

The apex angle of the thin prism

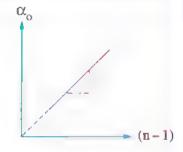

The refractive index of the prism material for the used light Slope =  $\frac{\Delta \alpha_0}{\Delta n} = A$ 

# Notes:

- (1) α in the thin prism doesn't depend on the first angle of incidence and it doesn't exceed 10°
- (2) The angle of deviation in the thin prism depends on the wavelength of the incident light  $(\lambda)$ .
- (3) When plotting a graph of deviation angle ( $\alpha_0$ ) for multiple thin prisms that have equal apex angles versus (n-1), the opposite graph will be obtained where:

Slope = 
$$\frac{\Delta \alpha_0}{\Delta (n-1)} = A$$

(4) To convert the value of an angle from degrees into radians and vice versa, we use the following relation:

$$\frac{\theta_{\rm rad}}{\pi} = \frac{\theta_{\rm deg}}{180}$$

And from the opposite table, we find that the sine of small angles ( $\sin \theta$ ) equals approximately the values of these angles in radians  $(\theta_{rad})$ :

$\theta_{\text{deg}}$	90°	60°	30°	10°	4°	10
sin θ	1	0.87	0.5	0.1736	0.0698	0.017
$\theta_{\rm rad}$	1.57	1.05	0.52	0.1746	0.0698	0.017

 $\theta_{\rm rad} = \sin \theta$ (At small angles)

#### Example 1

A thin prism has an apex angle of 7° and refractive index of 1.5. Calculate the angle of deviation of light in the prism.

#### Solution

$$A = 7^{\circ}$$

$$n = 1.5$$

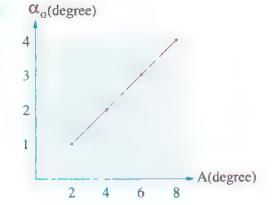

$$\alpha_0 = ?$$

$$A = 7^{\circ}$$
  $n = 1.5$   $\alpha_{\circ} = ?$   
 $\alpha_{\circ} = A(n-1)$ 

$$= 7 \times (1.5 - 1) = 3.5^{\circ}$$

#### Example 2

f he opposite graph depicts the relation between the deviation angle (a) of a light ray through multiple thin prisms which are made of the same material and the apex angle (A) for these prisms, calculate the refractive index of the material of which the prisms are made.

#### Solution

Slope = 
$$\frac{\Delta \alpha_{o}}{\Delta A} = \frac{4 - 2}{8 - 4} = 0.5$$

$$\alpha_0 = A(n-1)$$

:. Slope = 
$$n - 1 = 0.5$$

$$a = 1.5$$

#### Example 3

When a red light ray fell on a thin prism of apex angle  $\lambda$  and refractive index n. the ray deviated by an angle of 4° If the prism has been submerged in a liquid of refractive index 1.2, the angle of deviation becomes 2°

Calculate:

- (a) The absolute refractive index of the prism (n).
- (b) The apex angle of the prism (A).

#### Solution

$$(\alpha_0)_1 = 4^\circ$$

$$(\alpha_0)_1 = 4^\circ$$
  $n_{\text{liquid}} = 1.2$   $(\alpha_0)_2 = 2^\circ$   $n = ?$   $A = ?$ 

$$(\alpha_{\circ})_{\circ} = 2^{\circ}$$

$$A = ?$$

(a)

Before submerging the prism in the liquid

$$(\alpha_0)_1 = \mathbf{A}(\mathbf{n} + 1)$$

$$4 = \mathbf{A}(\mathbf{n} - 1)$$

After submerging the prism in the liquid

$$(\alpha_0)_2 = A \left(\frac{n}{n_{\text{liquid}}} - 1\right)$$

$$2 = \mathbf{A} \left( \frac{\mathbf{n}}{1.2} + 1 \right)$$

By dividing equation (1) by equation (2)

$$\frac{4}{2} = \frac{A(n-1)}{A(\frac{n}{1.2}-1)}$$

$$2\left(\frac{n}{1.2}-1\right)=n-1$$

$$\frac{2 n}{1.2} - 2 = n - 1$$

$$\therefore$$
 n = 1.5

(b) By substituting with the value of n in equation (1):

$$4 = A(1.5 - 1)$$

# 3

## Test yourself

Choose the correct answer:

A laser beam falls on a thin prism at multiple angles of incidence  $(\phi_1)$ , then in which of the following cases does the largest angle of deviation appear?

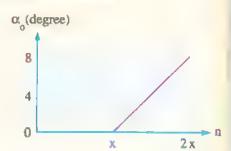

$$(a) \phi_1 = 4^\circ$$

$$(\hat{\mathbf{b}}) \phi_1 = 5^{\circ}$$

d All of them have the same deviation angle.

The opposite graph represents the relation between the angles of deviation ( $\alpha_0$ ) of a light ray and the refractive index (n) for multiple thin prisms that have equal apex angles (A), so the values of x and A are

	х	A
(a)	8	8
<b>b</b>	1	4
C	1	8
(d)	8	4

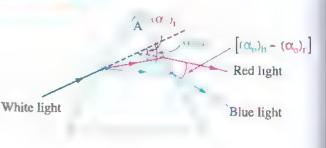

## 2

#### Angular dispersion

Dedocing the angular dispersion in this prise.

.. The thin prism is always in the position of minimum deviation and the angle of deviation (α<sub>0</sub>) depends on the refractive index (n) of the thin prism for the falling light ray which in turn depends on the wavelength (λ) of the falling light ray.

 $\therefore$  The angle of deviation ( $\alpha_0$ ) of the light ray changes by changing the wavelength ( $\lambda$ ) of the ray, so the thin prism disperses the white light into the visible spectral colors, where we can determine:

#### The angle of deviation of the red light

(the least angle of deviation for the colors of visible light)

#### The angle of deviation of the blue (violet) light

(the largest angle of deviation for the colors of visible light)

#### From the relation

Where

$$(\alpha_{o})_{r} = A(n_{r} - 1)$$
 1

$$(\alpha_o)_b = A(n_b - 1)$$
 2

 $(n_p)$  is the prism's refractive index for red  $(n_p)$  is the prism's refractive index for light

blue light

$$rac{1}{1} n_b > n_b$$

$$n_b > n_r$$
  $(\alpha_o)_b > (\alpha_o)_r$ 

By subtracting the two previous equations 1 and 2, we get the value of the angle between the two emergent rays (blue and red):  $(\alpha_o)_b - (\alpha_o)_r = A(n_b - 1) - A(n_r - 1)$ 

$$\therefore (\alpha_o)_b - (\alpha_o)_r = A(n_b - n_r)$$

• The value  $[(\alpha_a)_b - (\alpha_a)_r]$  is called the angular dispersion between the blue and the red rays.

#### The angular dispersion :-

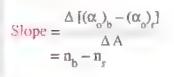

It is the angle between the extensions of the red and blue rays after their emergence from the thin prism.

It is the difference between the deviation angles of red and blue lights in the thin prism.

#### the factors on which the angular dispersion depends

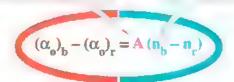

The apex angle of the prism (A) "directly proportional"

The prism's refractive indices for both blue and red lights  $(n_h - n_r)$ 

Slope = 
$$\frac{\Delta \left[ (\alpha_o)_b - (\alpha_o)_r \right]}{\Delta (n_b - n_r)}$$
= A

# Note

Yellow light is considered the intermediate between the blue and red lights, so we can define:

The average refractive index (n<sub>v</sub>).

It is the refractive index of yellow light (n<sub>v</sub>).

The average angle of deviation  $(\alpha_y)_y$ : It is the angle of deviation of yellow

From the relation

$$n_y = \frac{n_b + n_r}{2}$$

$$(\alpha_{o})_{y} = \frac{(\alpha_{o})_{b} + (\alpha_{o})_{r}}{2}$$

# Dispersive power

• Each transparent material if shaped as a thin prism has a characteristic dispersive power that distinguishes a material from another and it can be defined as follows:

The dispersive power  $(\omega_{\alpha})$ :...

It is the ratio of the angular dispersion between blue and red lights to the angle of deviation for the yellow light (the average angle of deviation).

## Pododký thi dispiráliú pôvět,

$$\therefore (\alpha_o)^p - (\alpha_o)^r = A(n^p - n^r)$$

$$\therefore (\alpha_{o})_{y} = A (n_{y} - 1)$$

$$\therefore \omega_{\alpha} = \frac{(\alpha_{o})_{b} - (\alpha_{o})_{r}}{(\alpha_{o})_{y}} = \frac{A(n_{b} - n_{r})}{A(n_{y} - 1)}$$

$$\omega_{\alpha} = \frac{n_{b} - n_{r}}{n_{y} - 1} = \frac{n_{b} - n_{r}}{\left(\frac{n_{b} + n_{r}}{2}\right) - 1}$$

Where:  $(n_y)$  is the refractive index of the prism for yellow.

**Notice that** dispersive power  $(\omega_{\alpha})$  is dimensionless

i.e., has no measuring unit because it is a ratio between two quantities of the same type having the same measuring unit.

#### The lucions on which

The prism's material refractive index only not on the apex angle of the prism nor the light angle of incidence on it.

Napaday per iyada ilkili ji biga daga

# Note:

 A rectangular glass block does not disperse light because it acts as two similar reversed triangular prisms; one counteracts the dispersion of the other.

#### Example 1

A thin prism has an apex angle of 8, its refractive index for red light is 1.52 and its refractive index for blue light is 1.54. Calculate:

- (a) The angle of deviation for each light color.
- (b) The angular dispersion for the light in the prism.
- (c) The dispersive power of the prism.

#### Solution

$$A = 8^{\circ}$$
  $n_r = 1.52$   $n_b = 1.54$   $(\alpha_o)_b = ?$   $(\alpha_o)_r = ?$ 

$$(\alpha_{o})_{b} - (\alpha_{o})_{r} = ?$$
  $\omega_{a} = ?$ 

(a) 
$$(\alpha_a)_b = A(n_b - 1) = 8 \times (1.54 - 1) = 4.32^\circ$$

$$(\alpha_n)_r = A(n_r - 1) = 8 \times (1.52 - 1) = 4.16^\circ$$

(b) 
$$(\alpha_0)_b - (\alpha_0)_r = 4.32 - 4.16 = 0.16^\circ$$

#### Another Solution:

$$(\alpha_{p})_{h} - (\alpha_{p})_{r} = A(n_{h} - n_{r}) = 8 \times (1.54 - 1.52) = 0.16^{\circ}$$

(c) 
$$n_y = \frac{n_b + n_r}{2} = \frac{1.54 + 1.52}{2} = 1.53$$

$$\omega_{\alpha} = \frac{n_b - n_r}{n_v - 1} = \frac{1.54 - 1.52}{1.53 - 1} = 0.038$$

a white light ray falls on this prism for one time with an angle of 30° and for another time with an angle of 60°, in which of the two cases is the dispersive power in the prism greater?

#### Mample 2

Two thin prisms have equal angular dispersions, the first prism is made of flint glass of werage refractive index 1.6 and dispersive power 0.036, while the second prism is made of crown glass of average refractive index 1.5 and dispersive power 0.028. If the apex angle of the second prism is 7, calculate the apex angle of the first prism.

#### Solution

$$(n_v)_1 = 1.6$$

$$(\omega_{\alpha})_1 = 0.036$$

$$(n_v)_2 = 1.5$$

$$(n_y)_1 = 1.6$$
  $(\omega_{\alpha})_1 = 0.036$   $(n_y)_2 = 1.5$   $(\omega_{\alpha})_2 = 0.028$   $A_2 = 7^{\circ}$   $A_1 = ?$ 

$$A_2 = 7^{\circ}$$

$$A_1 = ?$$

$$\therefore \ \omega_{\alpha} = \frac{n_{b} - n_{r}}{n_{v} - 1}$$

$$\therefore n_b - n_r = \omega_{\alpha} (n_y - 1)$$

- In the first prism:

$$(n_b)_1 - (n_r)_1 = (\omega_{\alpha})_1 ((n_y)_1 - 1) = 0.036 \times (1.6 - 1) = 0.0216$$

- In the second prism:

$$(n_b)_2 - (n_r)_2 = (\omega_{\alpha})_2 ((n_v)_2 - 1) = 0.028 \times (1.5 - 1) = 0.014$$

: They have the same angular dispersion:

$$\therefore A_{1} \left( (n_{b})_{1} - (n_{r})_{1} \right) = A_{2} \left( (n_{b})_{2} - (n_{r})_{2} \right)$$

$$A_1 \times 0.0216 = 7 \times 0.014$$

$$A_1 = \frac{7 \times 0.014}{0.0216} = 4.54^{\circ}$$

you are asked to calculate the apex angle of a prism of flint glass that causes the same deviation angle for yellow light as that caused by the second prism, what will be your answer?

# Test yourself

A thin prism has an apex angle of 10°, refractive index for red light 1.52 and for blue light 1.58. Calculate the angular dispersion and the dispersive power of the prism.

#### Choose the correct answer:

Two thin prisms x and y are made of the same material, the apex angle of prism x is A and its dispersive power is  $\omega_{\alpha}$ , so if the apex angle of prism y is 1.5 A, its dispersive power is .....

$$(\hat{a})\,\frac{\omega_{\alpha}}{2}$$

$$\stackrel{\text{\tiny{\textbf{b}}}}{\longrightarrow} \omega_{\alpha}$$

# From the previous, we can compare between the normal prism and the thin prism as follows:

	. The normal prism	The thin prism
The apex angle (A)	Large (more than 10°)	Small (less than 10°)
The refractive index (n)	$n = \frac{\sin \phi_1}{\sin \theta_1} = \frac{\sin \theta_2}{\sin \phi_2}$	$n = \frac{\alpha_0 + A}{A}$
The angle of deviation (α)	$\alpha = \phi_1 + \theta_2 - A$	$\alpha_o = A (n-1)$ Always at the minimum deviation angle
The manmum deviation position	One of the positions at which the triangular prism can be set in which its refractive index is given by: $n = \frac{\sin\left(\frac{\alpha_0 + A}{2}\right)}{\sin\left(\frac{A}{2}\right)}$	Always in the position of minimum deviation where the angle of deviation is determined from the relation: $\alpha_o = A(n-1)$
l ses	<ul> <li>Spectral dispersion of light into its components of wavelengths.</li> <li>As a reflecting prism in some optical devices such as periscope and binocular.</li> </ul>	Dispersion of light into its components of wavelengths.

- What happens when a beam of white light falls on a triangular prism adjusted in the minimum deviation position?
- 2 Explain the following statements:
  - (1) In the same triangular prism the angle of minimum deviation changes by the change of the wavelength of the passing light through it.
  - (2) When white light falls on a triangular prism, the deviation of the violet light will be greater than that of the red light.
  - (3) Triangular prisms disperse white light while the transparent cuboid slabs don't.
- 3 What are the factors on which the following quantities depend?
  - (1) The minimum angle of deviation in a triangular prism.
  - (2) The angle of deviation in the thin prism.
  - (3) The angular dispersion of light in a thin prism.
  - (4) The dispersive power  $(\omega_{\alpha})$  of a thin prism.
- What is the quantity that point (x) represents in each of the following graphs?
  - (a) The relation between the angle of deviation (α) of a light ray in a triangular prism and the first angle of incidence (φ<sub>1</sub>) for the light ray on one of the faces of the prism.
  - (b) The relation between the second angle of incidence (φ<sub>2</sub>) for a ray falling on a prism and the first angle of refraction (θ<sub>1</sub>).
  - (c) The relation between the angle of deviation (α) in different thin prisms that have equal apex angles and the refractive indices (n) for them.

CHAPTER

Hydrodynamics.

# **Chapter Four**

Hydrodynamics

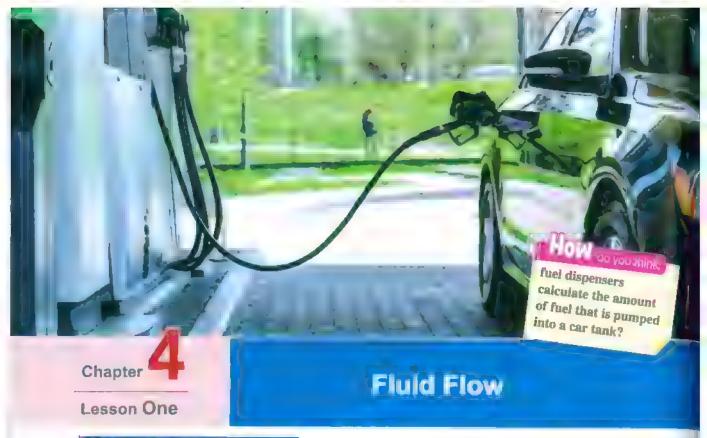

- 1 1 Fluid Flow.
- Test on Chapter 4.
- Approvalative Test on Chapters 1, 2 & 4.

#### Chapter objectives

#### By the end of this Chapter, the student should be able to:

- Distinguish between the steady flow and turbulent flow.
- Mention the characteristics of streamlines
- Mention the conditions of steady flow of a liquid.
- · Define the rate of flow
- Deduce the continuity equation
- Explain some applications of the continuity equation.

- Carry out some activities to explore the viscosity concept.
- · Explain viscosity.
- Know the concept of viscosity
   coefficient and its measuring unit
- Explain some applications of viscosity.
- Acquire the skills of solving problems on laws mentioned in this chapter

## The states of matter

You have studied in the previous years that matter can be found in one of three states:

Its molecules are tightly packed (the spaces between them are very small) and they are locked into their places in a regular pattern, so a solid has a definite shape and volume

Its molecules are close together with no regular arrangement and they can move and slide past each other, so a liquid doesn't have a definite shape and it takes the shape of its container, so it is called a fluid.

Its molecules are separated by relatively large spaces with no regular arrangement and they move freely at high speeds, so a gas doesn't have a definite shape but it takes the shape of its container, so it is called a tord.

Examples

Examples

Water and oil

Examples

Chlorine gas

#### From the previous, a fluid can be defined as follows:

#### A fluid: -

It is a material that can flow and has no definite shape, like liquids and gases.

Fluid

In this chapter, we will study only two of the properties of the moving fluids which are:

Flow Viscosity

And in this lesson, we will study the flow of liquids in some detail.

The flow of liquids is classified into two types:

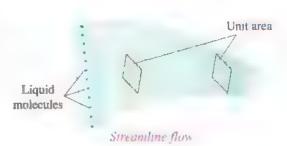

# Steady flow

When a liquid moves such that its adjacent layers slide smoothly over each other, we describe this motion as a laminar flow or a streamline (steady) flow, where every small amount of the liquid follows a continuous imaginary path called streamline.

#### Characteristics of streamlines:

- 1. They are imaginary lines that do not intersect.
- 2. The number of streamlines at any cross-section of the tube is constant.
- 3. The direction of the instantaneous velocity (v) of a small amount of a liquid at a certain point along a streamline is determined by the tangent of that streamline at that point.

4. The flow speed of a liquid at a point is determined by the density of streamlines at that point, so the speed of fluid flow increases by increasing the density of streamlines at that point and decreases by decreasing the density of streamlines.

Density of streamlines at a point : -

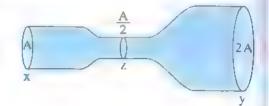

It is estimated by the number of streamlines that pass perpendicularly through a unit area surrounding that point.

#### Conditions of steady flow:

- 1. The speed of the liquid at one given point along the path of the liquid remains constant and does not change as time passes.
- 2. The flow is irrotational, i.e. there is no vortex motion.
- 3. No frictional forces exist between the layers of the liquid.
- 4. The flow rate of the liquid should be constant along its path because the liquid is incompressible and its density does not change with distance or time.
- 5. The liquid fills the tube completely such that the amount of liquid (volume and mass) that enters the tube at one end equals the amount of liquid that emerges from the other end in the same time interval according to the law of mass conservation.

#### Example

The opposite figure shows a liquid flowing steadily in a tube from one terminal to the other, so the ratio of the numbers of streamlines through the cross-sections x: y: z is ........

ra.2:1:4

**b** 1:2:4

(c) 2:4:1

(d) 1:1:1

#### Solution

In the steady flow, the number of streamlines through any cross-section of the tube remains constant.

.. The correct choice is (d).

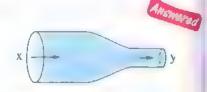

you are asked to determine, at which of the three cross-sections x, y or z, the density of the streamlines is higher, what will be your answer?

#### Test yourself

The opposite figure shows a liquid flowing steadily from terminal x to terminal y in a tube, determine if the following statement is true and explain your answer:

The speed of the liquid at terminal x =The speed of the liquid at terminal y

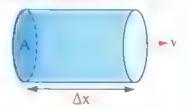

# Downing

• Consider a quantity of volume V<sub>ol</sub> and mass m of a liquid of density p flowing through a cross-sectional area of a tube A at velocity v, where it covers a distance Δx in time Δt as in the figure, then:

#### Density (p):

It is the mass of a unit volume of the material. It is measured in kg/m<sup>3</sup> and calculated from the relation:

$$\rho = \frac{m}{V_{ol}}$$

#### Volume flow rate (Q,)

Mass flow rate (Qm)

#### Concept

The volume of liquid that flows steadily through a definite cross-section of a tube in one second.

The mass of liquid that flows steadily through a definite cross-section of a tube in one second.

#### Deducing the equation

$$V_{ol} = A\Delta x$$

$$\therefore Q_v = \frac{V_{ol}}{\Delta t} = A \frac{\Delta x}{\Delta t}$$

$$Q_v = Av$$

$$m = \rho V_{ol} = \rho A \Delta x$$

$$\therefore Q_{m} = \frac{m}{\Delta t} = \rho A \frac{\Delta x}{\Delta t}$$

$$Q_{\rm m} = \rho A v$$

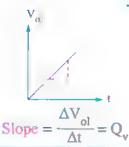

$$\therefore Q_{m} = \rho Q_{v}$$

#### Measuring unit

 $m^3/s$ 

kg/s

#### Graphical representation

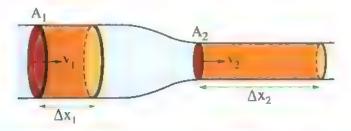

Slope = 
$$\frac{\Delta m}{\Delta t}$$
 =  $Q_m$ 

#### From the previous, we conclude that:

When the liquid flows steadily across a tube, the flow rate (volume or mass) will be constant at any cross-section of the tube.

# Deducing the continuity equation (the relation between the liquid flow speed and the cross-sectional area of the tube):

• Assume two different cross-sections of a tube that contains a liquid of density ρ, flowing steadily as in the following figure:

In the first cross-section  $(A_1)$  In the second cross-section  $(A_2)$ 

The volume flow rate 
$$Q_v = A_1 v_1 \qquad \qquad Q_v = A_2 v_2$$
 
$$Q_m = \rho A_1 v_1 \qquad \qquad Q_m = \rho A_2 v_2$$
 
$$Q_m = \rho A_2 v_2$$

- : The liquid flows steadily.
- .. The flow rate (volume or mass) is constant at any cross-section of the tube.

$$\therefore \rho A_1 v_1 = \rho A_2 v_2$$

$$\therefore \mathbf{A}_1 \mathbf{v}_1 = \mathbf{A}_2 \mathbf{v}_2$$

$$\therefore \frac{v_1}{v_2} = \frac{A_2}{A_1}$$
, this relation is called the **continuity equation**.

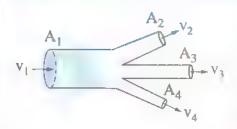

- $\therefore$  A =  $\pi r^2$ , where r is the radius of the tube cross-section.
- $\therefore \frac{v_1}{v_2} = \frac{r_2^2}{r_1^2} = \frac{d_2^2}{d_1^2}$ , where d is the diameter of the tube cross-section.

#### From the previous, we can conclude that:

The speed of a liquid that is flowing steadily in a tube at any point is inversely proportional to the cross-sectional area of the tube (as well as the square of the radius of the tube and also the square of its diameter) at that point.

#### \* When the liquid flows steadily in a tube that branches into a number of branches of:

#### Different cross-sectional areas

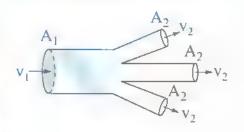

$$A_1 v_1 = A_2 v_2 + A_3 v_3 + A_4 v_4$$

$$r_1^2 v_1 = r_2^2 v_2 + r_3^2 v_3 + r_4^2 v_4$$

$$d_1^2 v_1 = d_2^2 v_2 + d_3^2 v_3 + d_4^2 v_4$$

#### The same cross-sectional area

then

$$A_1 v_1 = nA_2 v_2$$
(where n is the number of branches)
$$r_1^2 v_1 = nr_2^2 v_2$$

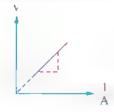

$$d_1^2 v_1 = nd_2^2 v_2$$

# Notes:

(1) When a liquid flows steadily in a tube of non-uniform cross-sectional area, we can represent the graphical relation between:

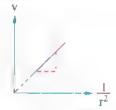

Speed of the liquid (v) and reciprocal of the cross-sectional area  $\begin{pmatrix} 1 \\ A \end{pmatrix}$ 

Speed of the liquid (v) and reciprocal of square of the cross-sectional radius  $\left(\frac{1}{r^2}\right)$ 

Slope = 
$$\frac{\Delta v}{\Delta \left(\frac{1}{A}\right)} = Q_v$$

As follows

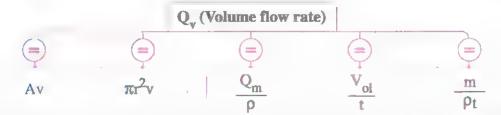

Slope = 
$$\frac{\Delta v}{\Delta \left(\frac{1}{r^2}\right)} = \frac{Q_v}{\pi}$$

(2) When opening multiple taps together to fill a container with a liquid such that the flow rate of the liquid from each tap is  $(Q_v)_1$ ,  $(Q_v)_2$ ,  $(Q_v)_3$ , then the total flow rate  $(Q_v)$  of filling the container is calculated from the relation:

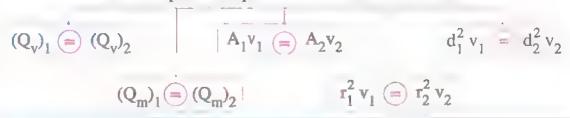

$$Q_v = (Q_v)_1 + (Q_v)_2 + (Q_v)_3$$

(3) When a liquid flows steadily in a tube, then at any cross-section of the tube;

(4) When a liquid flows in a tube with two different cross-sectional areas;

To compare the liquid flow at both cross-sections

#### Life applications of continuity equation:

#### I. The flow of blood in blood capillaries:

The speed of blood flow is faster in the main artery than that in blood capillaries because the sum of cross-sectional areas of the blood capillaries is greater than the cross-sectional area of the main artery, so the speed of blood flow decreases in the blood capillaries where

 $(v \propto \frac{1}{A})$ . Blood flow is slower in the blood capillaries to allow gases exchange (oxygen and carbon dioxide) with the tissues and supply them with nutrients.

#### 2. The design of gas burners holes:

The holes of the gas burners in the stoves are designed to be small so that the gas rushes out with high speed  $\left(v = \frac{1}{A}\right)$  to control the direction of flames.

#### 3. The design of the nozzle of the fire hose:

The fire hose is designed to end with a narrow nozzle so that water rushes out with high speed to reach far places quicker.

### Example II

Water flows from a water tap in the rate of 0.5 kg/s, so the time required to fill a container of volume  $2 \text{ m}^3$  using this tap is ..............

(Where:  $\rho_{water} = 1000 \text{ kg/m}^3$ )

(a) 
$$10^3$$
 s

(b) 
$$4 \times 10^3$$
 s

$$(c) 10^4 s$$

(d) 
$$4 \times 10^4$$
 s

### Solution

$$Q_{\rm m} = 0.5 \text{ kg/s}$$
  $V_{\rm ol} = 2 \text{ m}^3$   $\rho_{\rm water} = 1000 \text{ kg/m}^3$ 

$$V_{ol} = Q_{v} t$$

$$Q_m = PQ_v$$

$$\therefore t = \frac{V_{ol}}{Q_{v}} = \frac{V_{ol} \rho}{Q_{m}}$$

$$=\frac{2\times1000}{0.5}$$

$$=4\times10^{3}$$
 s

.. The correct choice is (b).

the water flow rate from the tap is 0.5 liter/s, will this change the time required to fill the container?

### Example 2

The opposite figure shows a water container of volume  $V_{ol}$  which can be filled using two water taps x and y such that if only tap x is used, the container takes 15 minutes to be filled but if only tap y is used, the container takes 30 minutes to be filled, then the time required to fill the container by using the two taps x and y together is ......

- a 5 minutes
- (b) 10 minutes
- © 15 minutes
- d 45 minutes

### Solution

$$t_x = 15 \text{ minutes}$$
  $t_y = 30 \text{ minutes}$   $t - 1$ 

$$Q_v = (Q_v)_x + (Q_v)_v$$

$$\frac{V_{ol}}{t} = \frac{V_{ol}}{t_{x}} + \frac{V_{ol}}{t_{y}}$$

 $\because$  The volume  $(V_{ol})$  of the container is constant.

$$\therefore \frac{1}{t} = \frac{1}{t_x} + \frac{1}{t_y} = \frac{1}{15} + \frac{1}{30} = \frac{1}{10} \text{ min}^{-1}$$

 $\therefore$  t = 10 minutes

... The correct choice is (b).

What a third tap z is used which individually fills the container in 10 minutes, so what is the required time to fill the container using the three taps together?

### Example 3

A liquid flows steadily in a tube as in the opposite figure. If the cross-sectional areas of x, y, z are A, A, 2 A respectively and the liquid speeds at the cross-sections x, y are v, 2 v respectively, then the liquid speed at z equals ...........

$$(\widehat{b} \frac{2}{3} v$$

$$|c||\frac{3}{2}v$$

### Solution

$$A_x = A$$
  $v_x = v$   $A_y = A$   $v_y = 2v$   $A_y = 2A$   $v_y = ?$ 

$$A_z \mathbf{v}_z = A_x \mathbf{v}_x + A_y \mathbf{v}_y$$

$$2 Av_{z} = A v + 2 Av$$
$$2 v_{z} = 3 v$$

$$2 v_{1} = 3 v_{2}$$

$$v_z = \frac{3}{2} v$$

.. The correct choice is (c).

### Example 4

A water pipe of diameter 2 cm in which water flows with a speed of 0.1 m/s. The pipe enters a house, where its diameter becomes 1 cm. Given that the density of water is 1000 kg/m<sup>3</sup>, calculate:

- (a) The speed of water in the pipe inside the house.
- (b) The volume and the mass of the water that flows every minute through any crosssection of the pipe.

### Solution

$$d_1 = 2 \text{ cm}$$
  $v_1 = 0.1 \text{ m/s}$   $d_2 = 1 \text{ cm}$   $t = 60 \text{ s}$   $\rho = 1000 \text{ kg/m}^3$ 

$$v_2 = ? V_{ol} = ? m = ?$$

(a) 
$$d_1^2 v_1 = d_2^2 v_2$$
  
 $(2)^2 \times 0.1 = (1)^2 \times v_2$   
 $v_2 = 0.4 \text{ m/s}$   
(b)  $V_{ol} = Q_v t = A_1 v_1 t = \pi r_1^2 v_1 t$   
 $= \frac{22}{7} \times (\frac{1}{2} \times 2 \times 10^{-2})^2 \times 0.1 \times 60$   
 $= 1.89 \times 10^{-3} \text{ m}^3$   
 $m = \rho V_{ol} = 1000 \times 1.89 \times 10^{-3} = 1.89 \text{ kg}$ 

### Example 5

The average speed of blood in one of the arteries of an adult person is 0.33 m/s. If the radius of that artery is 0.7 cm and it distributes blood to 30 smaller arteries each of radius 0.35 cm, then the average blood speed inside these small arteries equals . . . .

(a) 0.011 m/s

b 0.022 m/s

0.033 m/s

d, 0.044 m/s

### Solution

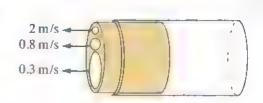

$$v_1 = 0.33 \text{ m/s}$$
  $r_1 = 0.7 \text{ cm}$   $n = 30$   $r_2 = 0.35 \text{ cm}$   $v_2 = ?$ 
 $A_1 v_1 = nA_2 v_2$ 
 $\pi r_1^2 v_1 = n\pi r_2^2 v_2$ 
 $(0.7)^2 \times 0.33 = 30 \times (0.35)^2 \times v_2$ 
 $v_2 = 0.044 \text{ m/s}$ 

### Example 6

.. The correct choice is d.

A tube of radius 5 cm ends with a stopper having 3 holes of radii 0.5 cm, 1 cm and 2.5 cm.

If the speeds of water when emerging out from the three holes are 2 m/s, 0.8 m/s and 0.3 m/s respectively as in the opposite figure, calculate:

- (a) The speed of water in the main tube.
- (b) The volume of the flowing water in the main tube during half a minute.

### Solution

$$r_1 = 5 \text{ cm}$$
  $r_2 = 0.5 \text{ cm}$   $r_3 = 1 \text{ cm}$   $r_4 = 2.5 \text{ cm}$   $v_2 = 2 \text{ m/s}$ 

$$v_3 = 0.8 \text{ m/s}$$
  $v_4 = 0.3 \text{ m/s}$   $t = 30 \text{ s}$   $v_1 = ?$   $v_{ol} = ?$ 

(a) : 
$$A_1 \mathbf{v_1} = A_2 \mathbf{v_2} + A_3 \mathbf{v_3} + A_4 \mathbf{v_4}$$
  
:  $r_1^2 \mathbf{v_1} = r_2^2 \mathbf{v_2} + r_3^2 \mathbf{v_3} + r_4^2 \mathbf{v_4}$   
(5)<sup>2</sup> ×  $\mathbf{v_1} = ((0.5)^2 \times 2) + ((1)^2 \times 0.8) + ((2.5)^2 \times 0.3)$   
 $\mathbf{v_1} = \mathbf{0.127} \text{ m/s}$ 

(b) 
$$V_{ol} = (Q_v)_1 t = A_1 v_1 t = \pi r_1^2 v_1 t$$
  
=  $\frac{22}{7} \times (5 \times 10^{-2})^2 \times 0.127 \times 30 = 0.03 \text{ m}^3$ 

# Test yourself

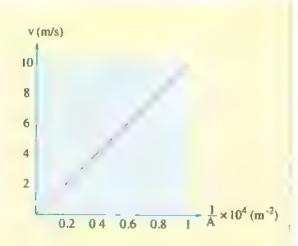

Water flows inside a tube of radius 2 cm with a speed of 1 m/s. Calculate each of the volume flow rate and the mass flow rate for the water in the tube.

(Given that: Water density = 1000 kg/m<sup>3</sup>)

### 2 Choose the correct answer:

- - $a \frac{1}{4} v$
- $\frac{1}{16}$  v
- C 4 v
- **d** 16 v
- - (a) 0.2 v
- (b) v
- © 2 v
- (d) 5 v

- $10^{-4} \, \text{m}^3/\text{s}$
- $10^{-3} \, \text{m}^3/\text{s}$
- $(c) 1 \text{ m}^3/\text{s}$
- $\overrightarrow{d}$  10 m<sup>3</sup>/s

# 2 Turbulent flow

- The turbulent flow is characterized by the presence of small eddy currents forming vortices as in the figure.
- The steady flow of a fluid becomes turbulent when:
  - The speed of the fluid exceeds a certain limit.
  - A gas transfers from a small space to a wider space or from high pressure to low pressure.

Eddy currents

Turbulent flow of the smoke

- (c) 10 m/s
- d 12.5 m/s

# Essay question

1 The opposite figure shows a liquid that flows steadily in a tube, determine which of the following ratios is greater than, less than or equal to one:

- (a) The ratio between the streamlines density at crosssection A and the streamlines density at cross-section B.
- (b) The ratio between the volume flow rate at cross-section A and the volume flow rate at cross-section B.
- The ratio between the mass flow rate at cross-section A and the mass flow rate at cross-section B.
- .1) The ratio between the speed of liquid flow at cross-section A and the speed of liquid flow at cross-section B.

### 2) Explain the following statements:

- 1) Streamlines in steady flow become crowded at the cross-section of high liquid speeds.
- In steady flow, the liquid flow rate is always constant at any cross-section of the tube.
- (3) In steady flow, the liquid flow is slow at the wider cross-section of the tube and fast at the narrower cross-section of the tube.
- The cross-sectional area of the water column flowing from the nozzle of a hose decreases when it is directed downwards and increases when it is directed upwards.
- (5) The openings of the gas stove are made small.
- In October War, the Egyptian Army used water pumps to rush water through hoses with narrow nozzles to open paths in Bar Lev Line, why do you think the hose nozzles should be narrow?
- 4 What are the results of the following men ion the reason dipossible).
  - A main artery is ended by a large number of blood capillaries concerning blood speed?
  - ? The end of a tube tapers to a narrow opening concerning the speed of the steady flow of the liquid?

## Dominion that recours high levels of thinking

### Choose the correct answer:

A water tank takes 10 minutes to be filled using three water taps together, takes 20 minutes when using the first water tap only and an hour when using the second water tap only, then the time required to fill the tank using the third water tap only is .....

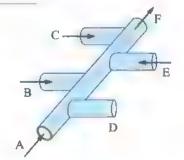

10 minutes

1 20 minutes

30 minutes

J 60 minutes

The opposite figure shows a tube that has different branches through which water flows steadily. If the volume flow rates at branches A, B, C, E and F are  $6 \text{ cm}^3/\text{s}$ ,  $3 \text{ cm}^3/\text{s}$ ,  $5 \text{ cm}^3/\text{s}$ ,  $4 \text{ cm}^3/\text{s}$  and  $3 \text{ cm}^3/\text{s}$ respectively, then ......

	Direction of water flow in branch D	Volume flow rate of water at D
(a)	into	7 cm <sup>3</sup> /s
(b)	into	15 cm <sup>3</sup> /s
(c)	out of	7 cm <sup>3</sup> /s
<b>d</b>	out of	15 cm <sup>3</sup> /s

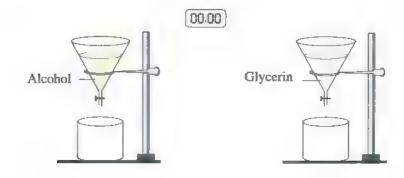

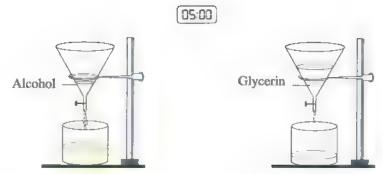

Liquids are characterized by general properties from which is the friction between the liquid layers during its flow. This friction produces a force that resists the sliding of the liquid layers above each other when it flows. This property is known as viscosity, where the concept of viscosity can be clarified through the following activities:

### Steps:

- 1. Suspend two identical funnels on two holders and put a beaker below each of them as shown in the following diagrams.
- 2. Pour a volume of alcohol in one of them and pour an equal volume of glycerin in the other and observe the flow of the two liquids from the funnels to the beakers.

### **Observation:**

You will notice that the flow rate of glycerin is less than the flow rate of alcohol.

i.e. The flow ability of glycerin is less than that of alcohol.

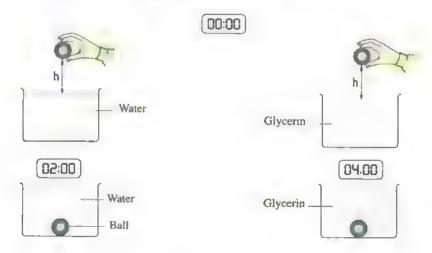

### Conclusion:

The viscosity of glycerin is higher than that of alcohol.

# Activity 2

### Steps:

- 1. Fill two beakers one with water and the other with glycerin.
- 2. Drop two small similar metal balls carefully, one in each of them from the same height.
- 3. Record the time taken by each ball to reach the bottom of the beaker.

### **Observation:**

- You will notice that the ball moves faster in water than in glycerin and reaches the bottom of water before the other ball reaches the bottom of glycerin.
- i.e. Glycerin resists the motion of the ball more than water.

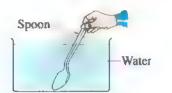

### Conclusion:

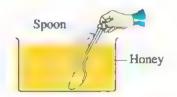

The viscosity of glycerin is higher than that of water.

# Activity 3

### Steps:

- 1. Fill two beakers one with water and the other with honey.
- 2. Stir both fluids by a spoon then take out the spoon.

### **Observations:**

- 1. You will notice that the spoon moves harder in honey than in water.
- 2. The motion of honey stops after removing the spoon within a short time interval while water continue to move for a longer time interval.
- i.e. The resistance of honey to the motion of bodies inside it is greater than that of water.

### Gonclusion:

The viscosity of honey is higher than that of water.

### From the previous, we conclude that:

The higher viscous liquid:

- 1. shows higher resistance to its own motion and its flow.
- 2. shows higher resistance to the motion of bodies through it.

### Viscosity can be defined as follows;

### Viscosity -

It is the property that causes a resistance or a friction between the liquid layers preventing them from sliding smoothly above each other.

## Explaining the concept of viscosity:

### There are two types of attraction forces between the molecules of matter:

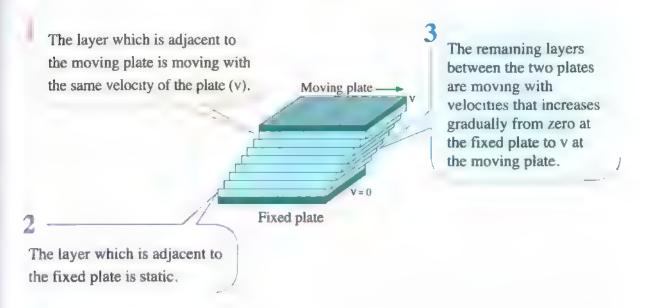

### 1. Cohesive forces:

Attraction forces between the molecules of the same substance like the attraction forces between the honey molecules.

### 2. Adhesive forces:

Attraction forces between the molecules of a substance and the molecules of another substance like the adhesive forces between the molecules of a drop of water and glass.

• Imagine a quantity of fluid confined between two parallel plates, one of them is static and the other moves with a velocity v as shown in the figure.

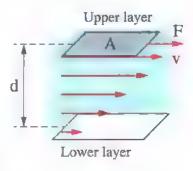

### This happens due to:

- 1. The presence of friction between each plate and the adjacent layer of liquid that results from the adhesive forces between the molecules of the solid plate and the molecules of the adjacent liquid layer, so the speed of every layer is equal to that of its adjacent plate.
- 2. The existence of another force between each liquid layer and the layer below it which resists the sliding of the liquid layers above each other causing a relative change in velocity between each layer and the adjacent layer.

This type of flow is called the laminar flow or viscous flow.

# Deducing the viscosity-coefficient:

Suppose two layers of a liquid separated by a perpendicular distance d, then a tangential force (F) acts on the upper layer of the liquid that has an area A causing a difference in velocity between the two liquid layers of magnitude v, hence in order to make the moving layer of the liquid keep moving with a constant velocity, the tangential force that acts on the upper layer has to be equal to the frictional forces between the layers of the liquid (force of viscosity) where this force is:

Directly proportional to the area of the moving layer

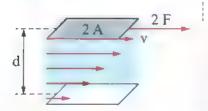

$$(F \propto A)$$

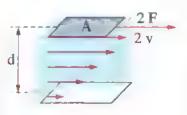

Directly proportional to the velocity difference between the two layers

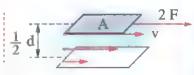

$$(F \propto v)$$

Inversely proportional to the perpendicular distance between the two layers

$$(F \propto \frac{1}{d})$$

$$\therefore \ F \propto \frac{Av}{d}$$

$$\cdot \cdot \quad F = \eta_{vs} \frac{Av}{d}$$

$$\therefore$$
 F = constant  $\times \frac{Av}{d}$ 

$$\dot{\eta}_{vs} = \frac{Fd}{Av}$$

Where:  $\eta_{us}$  is the viscosity coefficient that can be defined as:

### Viscosity coefficient:

It equals numerically the tangential force that acts upon a unit area of a liquid causing a velocity difference of one unit between two layers separated by a perpendicular distance of one unit.

The measuring unit of

kg/m.s

The factors affecting the viscosity coefficient

Temperature of the liquid (The liquid viscosity decreases as its temperature increases)

### Examples

At temperature 20°C:

$$(\eta_{vs})_{water} = 10^{-3} \text{ N.s/m}^2$$

$$(\eta_{vs})_{glycerin} = 1.5 \text{ N.s/m}^2$$

$$(\eta_{vs})_{honey} = 10 \text{ N.s/m}^2$$

Viscosity coefficient of water at temperature:

$$\Rightarrow$$
  $\eta_{ve} = 10^{-3} \text{ N.s/m}^2$ 

► t = 100°C 
$$\Rightarrow$$
  $η_{vs} = 0.28 \times 10^{-3} \text{ N.s/m}^2$ 

## The factors affecting the force of viscosity:

Area of the moving layer.

"Directly proportional"

Slope = 
$$\frac{\Delta F}{\Delta A} = \eta_{vs} \frac{v}{d}$$

Difference of velocity between two layers of the liquid.

"Directly proportional"

Slope = 
$$\frac{\Delta F}{\Delta v} = \eta_{vs} \frac{A}{d}$$

Viscosity coefficient for many different liquids or one liquid at different temperatures. F

"Directly proportional"

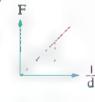

Slope = 
$$\frac{\Delta F}{\Delta \eta_{vs}} = \frac{Av}{d}$$

The perpendicular distance between the two layers.

"Inversely proportional"

Slope = 
$$\frac{\Delta F}{\Delta \left(\frac{1}{d}\right)} = \eta_{v_s} Av$$

### Example 1

In the opposite figure a ship moves in a still water lake, so the water speed is less at point

(a) x

(b)

© z

(d) k

# x · y · z ·

### Solution

The speed of the water layer decreases as we get closer to the static layer at the bottom of the lake.

- .. The lowest speed of water is at point k.
- :. The correct choice is (d).

### Example 2

A plane surface of area 0.5 m<sup>2</sup> moves at a uniform velocity of 2 m/s parallel to another static surface that is separated from it by a layer of liquid of thickness 4 cm, if the viscosity coefficient of the liquid is 1.5 kg m.s., then the force required to keep the surface moving with this uniform velocity is

- **b** 50 N
- © 67.5 N
- **d** 150 N

### Solution

$$A = 0.5 \text{ m}^2$$
  $v = 2 \text{ m/s}$   $d = 4 \text{ cm}$ 

$$v = 2 \text{ m/s}$$

$$d = 4 \text{ cm}$$

$$\eta_{vs} = 1.5 \text{ kg/m.s}$$

$$F = ?$$

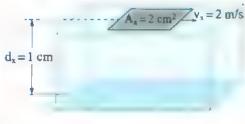

$$F = \eta_{vs} \frac{Av}{d} = \frac{1.5 \times 0.5 \times 2}{4 \times 10^{-2}} = 37.5 \text{ N}$$

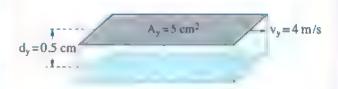

:. The correct choice is (a).

the temperature of the liquid is increased, does the force required to keep the uniform velocity of the plate which is mentioned in the example increase or decrease?

### Example 3

The following figures show two plane plates x, y each of them is placed above a layer of a liquid. If the force that acts on plate x = The force that acts on plate y, then the ratio between the coefficient of viscosity of the liquid below plate x and that below plate y  $(\eta_{vs})_x$  equals

- (a)  $\frac{1}{1}$
- (b)  $\frac{1}{10}$

 $\frac{10}{1}$ 

(d) 20

### Solution

$$A_{\perp} = 2 \text{ cm}^2$$

$$v_x = 2 \text{ m/s}$$

$$d = 1 \text{ cm}$$

$$A_x = 2 \text{ cm}^2$$
  $v_x = 2 \text{ m/s}$   $d_x = 1 \text{ cm}$   $A_y = 5 \text{ cm}^2$ 

$$v_y = 4 \text{ m/s}$$

$$d_v = 0.5 \text{ cm}$$
 F

$$v_y = 4 \text{ m/s}$$
  $d_y = 0.5 \text{ cm}$   $F_x = F_y$   $\frac{(\eta_{xx})_x}{(\eta_{xy})_x} = ?$ 

$$\because \eta_{vs} = \frac{Fd}{Av}$$

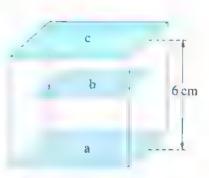

$$:: F_x = F_y$$

$$\therefore \frac{(\eta_{vs})_x}{(\eta_{vs})_y} = \frac{d_x A_y V_y}{d_v A_x V_x} = \frac{1 \times 5 \times 4}{0.5 \times 2 \times 2} = \frac{10}{1}$$

... The correct choice is (c).

### Example 4

The opposite figure shows three horizontal parallel plates a, b and c which are placed in a liquid of viscosity coefficient 0.8 kg/m.s. The two plates a, c are fixed while plate b is free to move and its area equals 4 cm<sup>2</sup>. If plate b is at a distance from one plate twice the distance to the other, then the required force to move plate b with a constant velocity of 5 m/s equals

(a) 
$$2.7 \times 10^{-4}$$
 N

(b) 
$$1.2 \times 10^{-3}$$
 N

### Solution

$$\eta_{vs} = 0.8 \text{ kg/m.s}$$
  $A_b = 4 \text{ cm}^2$   $d_{ac} = 6 \text{ cm}$   $d_{ab} = 2 d_{bc}$   $v_b = 5 \text{ m/s}$   $F_1 = ?$ 

### **Q** Clue

Plate b is affected by resistance forces of the liquid from above and below:

$$\therefore F_b = F_{ab} + F_{cb}$$

$$\begin{aligned}
d_{ac} &= d_{ab} + d_{bc} \\
6 &= 2 d_{bc} + d_{bc} \\
d_{bc} &= 2 cm \\
d_{ab} &= 6 - 2 = 4 cm \\
F_b &= F_{ab} + F_{cb} \\
&= \frac{\eta_{vs} A_b v_b}{d_{ab}} + \frac{\eta_{vs} A_b v_b}{d_{cb}} \\
&= \eta_{vs} A_b v_b \left(\frac{1}{d_{ab}} + \frac{1}{d_{cb}}\right) \\
&= 0.8 \times 4 \times 10^{-4} \times 5 \left(\frac{1}{4 \times 10^{-2}} + \frac{1}{2 \times 10^{-2}}\right) = 0.12 \text{ N}
\end{aligned}$$

### .. The correct choice is (c).

plate b was in the mid-distance between the plates a, c and moving with the same velocity, will the required tangential force to move the plate with the same previous uniform velocity change?

### Applications of viscosity

### 1. Lubrication of machines.

- Machines should be lubricated from time to time, to decrease the heat produced due to friction and to protect the machine parts from corrosion and increase its efficiency.
- Highly viscous oils are used due to their strong adhesive forces with the machine parts, since they do not seep away or sputter from the machine parts during motion.

## Note:

• Water cannot be used in lubrication because it has low viscosity, so it seeps away from the machine parts due to the weak adhesive force with the machine parts.

### 2. Saving fuel consumption in moving vehicles.

- The rate of fuel consuming in a moving vehicle depends on:
- Motion of the vehicle with an acceleration (changing velocity).
- 2. Friction forces with:
  - The road.
  - Air (air resistance to the motion of the vehicle).
     When the vehicle moves in a uniform velocity (acceleration = zero), so if this velocity is:

### Low or medium

The air resistance due to air viscosity is directly proportional to the vehicle speed, so the fuel consumption becomes in certain rate.

### Higher than a certain limit

The air resistance due to air viscosity becomes directly proportional to the square of the vehicle speed, so the fuel consumption becomes much higher.

So, the expert driver of the vehicle limits the vehicle speed to reduce fuel consumption.

# 3. In medicine, blood precipitation rate test (The terminal velocity of falling of the red blood cells in plasma).

When a ball undergoes a free fall in a liquid, it is affected by three forces:

- Its weight.
- Buoyancy (upthrust force) of the liquid.
- Friction between the ball and the liquid due to viscosity.

  So, the velocity of the ball increases gradually till it attains a constant terminal velocity due to the balance of these three forces. The terminal velocity

Liquid resistance to Upthrust force of the liquid

Weight of the ball

increases as the radius of the ball increases, so it can be determined if the volume of the red blood cells was normal or not by taking a blood sample and measuring its precipitation rate which is proportional to the terminal velocity of the falling red blood cells in the plasma, for example:

### When

The precipitation rate is greater than normal

The precipitation rate is lower than normal

### it indicates that

Red blood cells adhere together, so their volume and radius increase.

Red blood cells break down, so their volume and radius decrease.

### so, the terminal velocity of blood cells

becomes higher

becomes lower

like the case of

Rheumatic fever

Anemia

### Enrichment Information

### The normal precipitation rate:

The normal precipitation rate for the red blood cells ranges between 0 : 22 mm/h for men and 0 : 29 mm/h for women.

# Test yourself

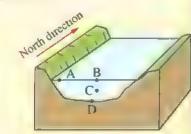

Is it better to design ships with large bottom area or with the smallest possible bottom area? Explain your answer.

### Choose the correct answer:

- (1) A square plate of side length d moves with a uniform velocity of x m/s on the surface of a liquid of depth 2 d when it is affected by a tangential force x newton, so the viscosity coefficient of the liquid equals . kg.m<sup>-1</sup>.s <sup>1</sup>
  - $a \frac{1}{2 d}$
- $\bigcirc \frac{d}{2}$

- $\frac{2}{d}$
- $\frac{d}{d^2}$

(2) The opposite figure shows a cross-section in the Nile River. In this section the river flows to the north. At which of the shown points in the figure is the greatest flow speed?

- (a) At point A
- (b) At point B
- C At point C
- (d) At point D
- (3) A plate of area A slides with a uniform velocity on the water surface in two cases as shown in the figures (1), (2), so the ratio between the forces (F<sub>1</sub>/F<sub>2</sub>) that are

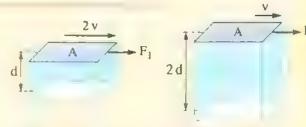

Figure (1)

Figure (2)

required to keep the plate moving in the same velocity in each case equals

 $\frac{a}{1}$ 

 $\bigcirc \frac{1}{2}$ 

 $\bigcirc \frac{2}{1}$ 

 $\frac{4}{1}$

### Multiple choice questions

- 1 The resistance of a liquid to the motion of objects inside it is a result of .......
  - (a) the liquid density

b the liquid viscosity

the weight of the liquid

- d the buoyant force of the liquid
- 2 If the speed difference between two liquid layers gets decreased when a tangential force is acting on the upper layer, then at the same temperature the viscosity coefficient.
  - (a) vanishes

(b) decreases but doesn't vanish

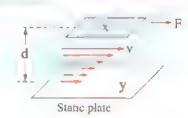

(c) increases

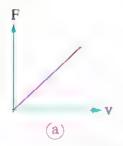

- (d) remains constant
- (3) When the temperature of a liquid decreases, its viscosity coefficient ....
  - (a) increases

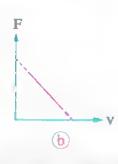

(b) decreases

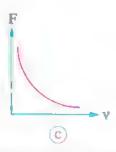

c does not change

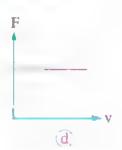

- d depends on the type of liquid
- Which of the following graphs represents the relation between the force (F) which is required to move plate x with a uniform velocity v on the surface of a liquid parallel to a static plate y and the speed (v) of plate x?

- When a metallic ball falls through a liquid in a jar, the viscosity force of the liquid which is acting on the ball depends on ...........
  - (a) the ball radius

(b) the liquid density

c the ball mass

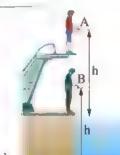

d) the liquid quantity

- \*When a swimmer jumps into water and reaches a certain depth then rise again to the surface, the force that changes its direction will be ....
  - (a) the swimmer weight
  - b the frictional force between the swimmer and water
  - (c) the buoyant force of water that acts on the swimmer
  - (d) all of these forces
- A metallic ball has fallen once through water and another time through honey. If the average frictional force between the ball and water is F<sub>1</sub> and between the ball and honey is F<sub>2</sub>, then which of the following statements for F<sub>1</sub>, F<sub>2</sub> is correct?
  - (a)  $F_1 = F_2 = 0$
- (b)  $F_1 = F_2 \neq 0$
- $\bigcirc F_1 > F_2$
- $\bigcirc F_1 < F_2$
- B During the free fall of a body from the top of a building towards the ground, the frictional force between the body and air .........
  - (a decreases

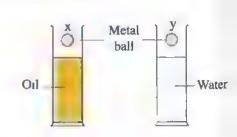

(b) increases

c doesn't change

- d decreases then increases

- (a) t, because it covers the same distance
- b less than t because the viscosity of water is less than that of air
- c greater than t because the viscosity of water is greater than that of air
- d greater than t because the weight of the ball is greater in water
- The opposite figure shows two identical metal balls (x, y) falling from the same height into two identical jars containing similar volumes of oil and water till reaching the bottoms, then the average speed of ball x is . ........

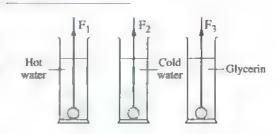

- a greater than the average speed of ball y
- b less than the average speed of ball y
- c equal to the average speed of ball y
- d equal to its instantaneous speed at the bottom of the jar

- A viscous liquid flows steadily in a cylindrical tube. If the liquid speed along the tube axis is v, then the speed of the liquid layer which touches the tube walls equals ......
  - (a) 2 v

(d) zero

The opposite figure shows three identical metal balls, each of them is tied by a thread and placed at the bottom of one of three similar cylinders that contain three equal volumes of different liquids. Through which of these liquids the ball faces a greater resistance when it gets pulled out from the liquid with the same uniform speed?

- (a) In the hot water.
- (c) In glycerin.

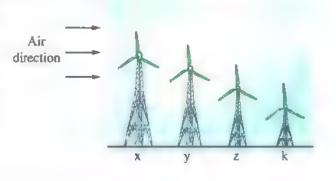

- (b) In the cold water.
- (d) The same force in all cases.
- 13. The opposite figure shows four windmills of identical turbines and blades installed near each other at different heights to be used for generating electricity, so the windmill that has the greater potential of generating electricity will be ......

(b) y

(c) z

(d)k

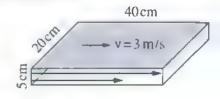

- [4] At relatively low or medium speeds of a car, the air resistance due to air viscosity is .... .
  - directly proportional to the square of the speed of the car
  - b directly proportional to the speed of the car
  - inversely proportional to the square of the speed of the car
  - (d) inversely proportional to the speed of the car
- 15 At high speeds of a car, the air resistance due to air viscosity is ....
  - (a) directly proportional to the speed of the car
  - (b) inversely proportional to the speed of the car
  - e directly proportional to the square of the speed of the car
  - d inversely proportional to the square the speed of the car

- (6) Two cars (x, y) have travelled for the same distance with different speeds of 20 km/h and 160 km/h respectively. If the amount of fuel consumed in car x to cover this distance is Q, then the amount of fuel consumed in car y to cover the same distance is · · · · · ·
  - (a) equal to Q

(b) greater than Q

c) less than Q

- d indeterminable
- \* In the opposite figure, if a tangential force of 10 N acted upon the upper plate to move it at a uniform speed of 3 m/s, then the viscosity coefficient of the liquid equals .....

- 1 0.021 N.s/m<sup>2</sup>
- $0.48 \text{ N.s/m}^2$
- $0.75 \text{ N.s/m}^2$
- 1 2.08 N.s/m<sup>2</sup>
- (B) A circular plate of radius 7 cm slides at a uniform speed of 0.1 m/s on a ceramic floor covered with a layer of viscous liquid of thickness 2.5 mm and viscosity coefficient 2.5 N.s/m<sup>2</sup>, then the tangential force acting on the plate is .....
  - (a) 1.54 N
- **b** 1.32 N
- @ 1.24 N
- 19 A rectangular plate of dimensions 50 cm, 25 cm is affected by a tangential force of 15 N which moves it at a constant speed of 0.8 m/s on a layer of viscous liquid of thickness 9.375 mm, so the viscosity coefficient of the liquid is .....
  - 0.42 kg/m.s
- 0.85 kg/m.s
- 1.41 kg/m.s
- . 2.31 kg/m.s
- When a tangential force F acts on a plate of area A placed on another static plate where a layer of liquid of thickness d is in between, the upper plate moves with a uniform velocity v. What is the tangential force that makes the upper plate moves with a constant velocity 2 v under the same conditions?
  - a F

- (b)2F

- Two plates x, y move on the surface of a liquid with constant velocities  $v_x$ ,  $v_y$  respectively by the effect of constant tangential forces of equal magnitudes F as in the opposite figure, then the ratio between the two speeds  $\left(\frac{\dot{x}}{v}\right)$ equals .....
  - 환수

- Liquid 2d

- \* A layer of a viscous liquid of thickness 8 cm is put between two parallel horizontal plane plates. If the viscosity coefficient of the liquid is 0.8 kg/m.s, then the force required to move a thin plate of area 0.5 m<sup>2</sup> between the two plates, parallel to them with a uniform speed of 2 m/s and at a distance of 2 cm from one of them equals = .
  - (a) 13.33 N
- 6 26.67 N
- (c · 40.52 N
- 6 53.33 N
- \* A layer of thickness x of a liquid of viscosity 0.2 kg/m.s is confined between two plates, one of the plates is static and the other which has an area of 2 cm<sup>2</sup> is moving with a uniform velocity such that it covers a distance 100 x through a time interval of 4 s, so the required force to move the plate equals ......
  - a 10 N
- (b) 10<sup>-3</sup> N (c) 10<sup>-4</sup> N
- (d 0.1 N
- The opposite figure shows a boat pulling a skater to move with a uniform velocity v, if the tangential force which is acting on the boat is F, and the tangential force which is acting on the skating board is F2, then .......

- $(a)F_{1} > F_{2}$
- b F, < F,
- $c_1F_1 = F_2 = 0$   $(d_1F_1 = F_2 \neq 0)$

### Essay questions

- Explain the following statements:
  - (1) Aqueous plants grow close to the riverbanks.
  - (2) The speed of the sea waves decreases as they get closer to the shore.
  - (3) People who are living in high floors feel the wind speed more than those who are living in the ground floor.
  - (4) As the viscosity of a liquid increases, its resistance to the motion of a solid body inside it increases.
  - (5) A liquid restores its static condition after a while of stirring it.
  - (6) It is hard to swim against the current in the middle of the river.
  - (7) Moving an object in water is harder than it is in air.
  - (8) It is very important to use oil to lubricate the metallic machines regularly.

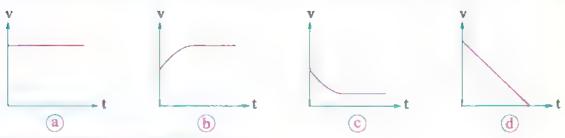

- (9) Engine oils that are used in summer must be more viscous than those which are used in winter.
- (10) Using materials of high viscosity to lubricate the metallic machines.
- (11) Water is not suitable to lubricate the metallic machines.
- (12) The sedimentation rate of red blood cells decreases in anemia patients.
- (13) The sedimentation rate of red blood cells increases in rheumatic fever patients.
- (14) Doctors can diagnose some diseases through sedimentation rate test.
- What are the results of each of the following, give reasons:
  - (1) Increasing the area of a plate that moves with a constant speed in a viscous liquid to the double, concerning the required tangential force to move the plate.
  - (2) Decreasing the temperature of a liquid, concerning its viscosity.
  - (3) Not lubricating the moving machines regularly.
  - (4) Exceeding a certain limit for the car speed, concerning the fuel consumption.
- In which case does the submarine need a larger force to push it with a certain uniform velocity v, under water or while floating?

# Questions that measure high frield of thinking

### Choose the correct answer:

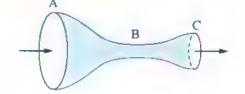

### Answer the following questions:

During a Nile cruise from Aswan to Cairo, the ship captain sails the ship in the middle of the river stream but during the return from Cairo to Aswan he sails close to the shore. How do you explain this? (White

### Choose the correct answer

The opposite figure shows a liquid flowing steadily in a tube, at which section the flow speed of the liquid is higher?

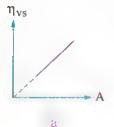

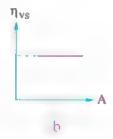

- (a) Section A
- (b) Section B
- © Section C
- d The speed is the same at the three sections.
- 2 When a person gets infected with rheumatic fever, what happens to the volume of the red blood cells and its final velocity during its precipitation in the plasma?
  - a increases, increases

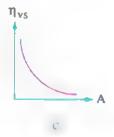

b increases, decreases

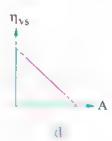

c decreases, decreases

- d decreases, increases
- Which of the following graphs represents the variation of the viscosity coefficient ( $\eta_{vs}$ ) of a liquid versus the change of surface area (A) of the plate for multiple plates that are moving with a uniform velocity over the liquid surface?

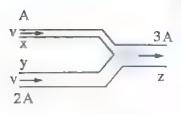

- Water flows steadily in a pipe that is connected to a hose. If the ratio between the radius of the hose and the radius of the pipe is  $\frac{2}{3}$ , the ratio between the speed of water in the hose to the speed of water in the pipe is ....
  - (a)  $\frac{4}{9}$

ⓑ  $\frac{2}{3}$ 

© 9/4

 $\frac{3}{2}$ 

- The opposite figure shows a liquid flowing steadily in a tube, so ......
  - (a) the density of streamlines at x is less than at z
  - b the speed of the liquid at y is less than at z
  - (c) the volume flow rate at x is greater than at z
  - d the speed of the liquid at z equals its speed at y

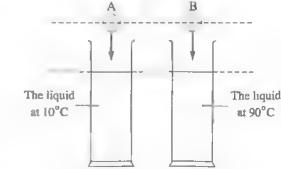

- 6 Three taps are used for filling a basin, hence to fill the basin, the first tap alone takes an hour and the second alone takes a  $\frac{1}{2}$  hour while the third takes  $\frac{1}{4}$  hour, so the time required to fill the basin using the three taps together will be .
- **b**  $\frac{3}{4}$  hour **c**  $\frac{7}{9}$  hour **d**  $\frac{7}{9}$  hour
- 7. A plate of surface area 0.25 m<sup>2</sup> slides at a constant speed of 0.6 m/s above a layer of a viscous liquid of thickness 5 mm. If the viscosity coefficient of the liquid is 0.95 N.s/m<sup>2</sup>, the tangential force that acts on the plate equals ...
  - a) 14.25 N
- (b) 21.375 N
- (c) 28.5 N
- (d) 42.75 N
- 8 Water flows steadily through a horizontal pipe to a narrow section of radius half that of the other section, so the mass flow rate through the narrow section ......
  - decreases to quarter

b decreases to half

increases to quadruple

- (d) remains constant
- A drip irrigation system is used to drip water through 1000 identical holes, each of crosssectional area 8 mm<sup>2</sup>. If the average speed of water flow from each hole is 2 m/s, the volume flow rate in the main tube equals .......
  - $(a) 0.08 \text{ m}^3/\text{s}$
- (b)  $0.016 \text{ m}^3/\text{s}$
- $(c) 0.32 \text{ m}^3/\text{s}$
- (d) 0.064 m<sup>3</sup>/s

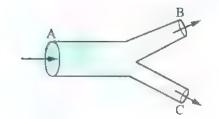

10 The opposite figure shows two metal balls (A, B) falling into two identical cylinders containing equal volumes of the same liquid with different temperatures, which of the two balls reaches the bottom of the cylinder first?

- (a, Ball A
- h' Ball B
- The two balls reach the bottom at the same instant
- d The two balls will never reach the bottom

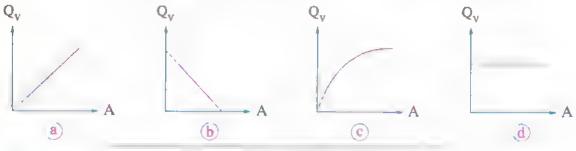

11) The opposite diagram shows a liquid flowing steadily in a tube. If the volume flow rates in branches B and C are 0.1 m<sup>3</sup>/s and 0.3 m<sup>3</sup>/s respectively, the volume flow rate at the cross-section A equals ......

- (a)  $0.1 \text{ m}^3/\text{s}$
- (b)  $0.2 \text{ m}^3/\text{s}$
- (c) 0.3 m<sup>3</sup>/s
- $(d) 0.4 \text{ m}^3/\text{s}$
- (2) A hose has a cross-sectional area 25 cm<sup>2</sup> at the water source and 5 cm<sup>2</sup> at its end. If water flows steadily in the hose with a speed of 0.4 m/s at the water source, the mass of the flowing water through 15 minutes from the hose end equals ...... ( $\rho_{\text{water}} = 1000 \text{ kg/m}^3$ )
  - (a) 500 kg

- (b) 900 kg (c) 2000 kg
- A liquid flows steadily in a tube that have different cross-sectional areas. Which of the following graphs represents the relation between the volume flow rate (Q<sub>v</sub>) of the liquid and the cross-sectional area of the tube (A)?

- A cylindrical syringe is attached to a metallic needle of cross-section 0.1 mm<sup>2</sup> and the solution flows through it with a rate of 10<sup>-8</sup> m<sup>3</sup>.s<sup>-1</sup>. So, the flow speed of the solution through the needle is equal to
  - (a) 0.1 m/s
- (b) 0.4 m/s
- © 0.5 m/s

The following table depicts the relation between the speed of a liquid (v) at a point in a pipe and the cross-sectional area of the pipe at the same point:

v (m/s)	60	30	15	6
A (cm <sup>2</sup> )	1	2	4	10

- Plot the relation between (v) on the vertical axis and  $(\frac{1}{A})$  on the horizontal axis.
- (b) From the graph find:
  - 1- The speed of the liquid at a cross-section of 5 cm<sup>2</sup>.
  - 2- The volume flow rate of the liquid.

The prism in the figure is made of crown glass.

Its refractive index ranges from 1.517 for the longest visible wavelength to 1.538 for the shortest one.

Find the range of refraction angles for the light transmitted into air through the right side of the prism.

White light 60° 60°

# Test

## For the first month

Choose the correct answer (1:9):

A light ray is incident on a mirror where it makes an angle of 30° with it, so the angle between the incident and the reflected rays is equal to .....

1 20°

(b) 60°

(C) 120°

(d) 150°

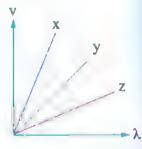

The opposite graph represents the relation between the speed (v) and the wavelength  $(\lambda)$  for three waves x, y, z when they propagate in three different media, so the correct order for the periodic time for the waves is .....

$$b_x T_z > T_x > T_y$$

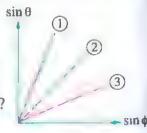

$$T_z > T_y > T_x$$

When using two different light sources the ratio between their wavelengths  $\left(\frac{\lambda_1}{\lambda_2} = \frac{7}{8}\right)$ in Young's double slit experiment, the ratio between the distance between the centers of two successive fringes of the same type in the two cases  $\begin{pmatrix} \Delta y_1 \\ \Delta y_2 \end{pmatrix}$  will be ..........

A light beam transfers from air to three different media (1), (2) and (3) one at a time and the opposite graph represents the relation between sine of the angle of refraction (sin  $\theta$ ) for the light ray in each medium and sine of the angle of incidence (sin  $\phi$ ) for the beam, which of the three media has the highest refractive index?

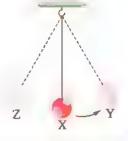

Medium (1)

(h Medium (2)

Medium (3)

The three media have the same refractive index.

In the opposite figure, a simple pendulum moves a simple harmonic motion of periodic time T where it starts its motion from point X in the direction of point Y, so the point at which the pendulum bob be after a time 1.75 T is ............

point X

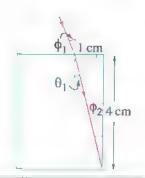

h point Y

point Z

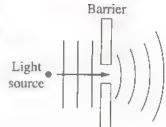

between the two points X, Y

- A light ray transfers from air to a medium of absolute refractive index 1.6 as in the opposite figure, so the angle of the incidence  $(\phi_1)$  of the ray equals.
  - 15.2°
- h 22.8°
- 10 28.5°
- od 34.2°

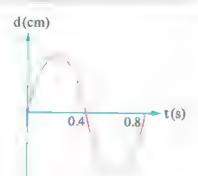

The opposite figure represents the diffraction phenomenon for a light ray of wavelength (λ) and frequency (υ) passing through a slit of width d in a barrier, so to make the diffraction more clear, we have to ........

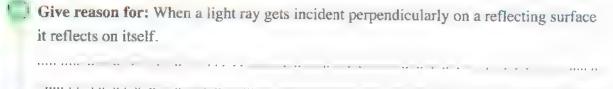

use a light of frequency less than v

- b use a light of wavelength less than λ
- increase the distance between the light source and the barrier
- If the speeds of light in two media are  $3 \times 10^8$  m/s,  $2 \times 10^8$  m/s, so the relative refractive index from the optically rarer medium to the optically denser medium equals .............
  - 'a , 0.67
- h 0.83
- 1.2
- d 1.5
- The opposite graph represents the relation between displacement (d) of one of the molecules of a medium through which a transverse wave is propagating with a speed of 20 m/s and time (t), so the wavelength of that wave equals

- 4 m
- 1 8 m
- ' 16 m
- ′√ 25 m
- Answer the following questions (10: 12):

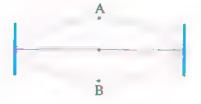

0	In Young's double slit experiment, a laser ray of wavelength 575 nm is used where the screen on which the fringes are received is placed at a distance of 0.9 m from the barrier of the double slits, so the center of the first bright fringe becomes at 2.75 mm from the center of the central fringe. Calculate the distance between the slits.
0	A lood got appropriately a graing goil go the length of the goil become 7 am and when
<b>W</b>	A load got suspended by a spring coil, so the length of the coil became 7 cm, and when the load gets pulled vertically downwards by a certain force, the length of the coil
	becomes 10 cm. If the load is left to vibrate, calculate the distance covered by the load through five complete vibrations.

# Test 2

# For the first month

#### Choose the correct answer (1:9):

- (a) 20 Hz
- (c) 100 Hz

- **b** 50 Hz
- (d) 200 Hz
- In Young's double slit experiment, the fringe that is formed due to superposition of two waves between which the path difference is zero will be the ......... fringe.
  - (a) central

**b** first bright

(c) first dark

- d second bright
- A light ray of speed c gets incident on a mirror, so it gets reflected with a speed ............
  - пјс

(b) greater than c

less than c

- d) the answer is indeterminable
- When a wave transfers between two different media, which of the following do not get altered for that wave?
  - (a) The speed and the frequency
- b The wavelength and the periodic time
- The speed and the wavelength
- d The frequency and the periodic time

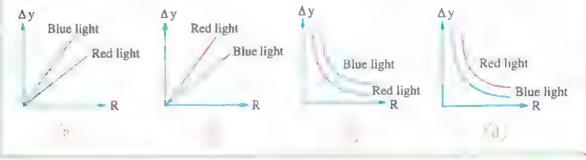

- $n_1 > n_2$
- (b)  $n_1 = n_2$
- © n<sub>1</sub>< n<sub>2</sub>
- d the answer is indeterminable

What's the type of the wave that will be formed in the spring coil and in the air when the two branches of the tuning fork in the opposite figure vibrate?

	In the spring coil	In air
ci	Longitudinal	Transverse
b	Longitudinal	Longitudinal
C,	Transverse	Transverse
d	Transverse	Longitudinal

Young's double slit experiment is conducted two times, the first using red light and the second using blue light. In each time, the distance between the double slit and the fringes' receiving screen is changed many times. So, which of the following figures represents the graph of the distance between the centers of two successive dark fringes (\Delta y) versus the distance between the double-slit barrier and the fringes receiving screen (R)?

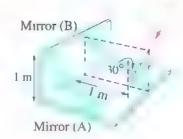

The opposite figure represents a load attached to one of the ends of a spring and moves in a simple harmonic motion between two points A, D Which of the following quantities becomes minimum when the object becomes at point O?

- Speed of the object.
- b Elastic potential energy of the object.
- Kinetic energy of the object.
- . Mechanical energy of the object.

gets incident on mirror B with an angle of incidence 30° gets incident on mirror B with an angle of incidence 60° gets reflected on mirror B with an angle of incidence 45°

d does not get incident on mirror B

#### Answer the following questions (10: 12):

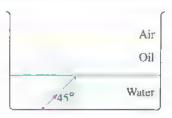

The opposite figure represents bright and dark fringes that are formed due to one of the physical phenomena of light.

What is this phenomenon? And why?

- A spring coil is moved in a way to make a wave of wavelength 120 cm and periodic time of 0.4 s, then it is moved in a different way to make a wave of wavelength 210 cm that has the same speed of the first wave, calculate the periodic time of the second wave.
- In the opposite figure, a point light source is placed in water from which a light ray gets incident by angle 45° on the boundary surface between water and oil.

  If the absolute refractive index of water is  $\frac{4}{3}$  and the absolute refractive index of oil is 1.8, then calculate angle of refraction of the light ray in air.

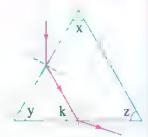

# Test

## For the second month

#### Choose the correct answer (1:9):

An incident light ray on a triangular prism gets refracted inside the prism then gets emerged away from the normal as in the opposite figure, so the apex angle of the prism is .............

(a) z

(b) k

(c) y

d x

A light ray is incident on a fiber optic cable that is made of a flexible material of refractive index 1.66, so the maximum angle of incidence of the light ray on the internal surface to get out of the cable equals approximately .....

a 37°

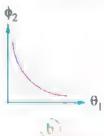

(b) 45°

€ 63°

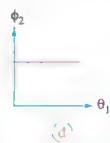

(d) 90°

Which of the following graphs represents the relation between the second angle of incidence  $(\phi_2)$  and the refraction angle  $(\theta_1)$  for a light ray that gets incident on the face of a triangular prism with different angles of incidence?

 $\theta_2$   $\theta_1$ 

θ<sub>2</sub>

A light ray gets incident perpendicularly on one of the faces of a triangular prism of apex angle 41.8°, so it gets emerged tangent to the opposite face, hence the refractive index of the prism material is .............

(a) 1.3

(b) 1.5

@ 1.7

A sound wave transfers from air to iron. If the ratio between the speed of sound in air and the speed of sound in iron is  $\frac{3}{44}$  while the wavelength of that sound wave in air is 57.6 cm, then its wavelength in iron is  $\frac{3}{44}$  while the wavelength of that sound wave in air is

(a) 3.9 cm

(b) 172.8 cm

© 533.5 cm

(d) 844.8 cm

The opposite graph shows the relation between the angle of deviation of a light ray ( $\alpha$ ) and the angle of incidence ( $\phi_1$ ) of this light ray on one of the faces of a triangular prism, then the apex angle of the prism and its refractive index are

(a) 60°, 1.5

b 80°, 1.45

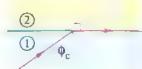

· respectively.

(c) 75°, 1.5

d 80°, 1.35

In the opposite figure, a light ray falls from medium 1 on the separating surface between the two media 1 and 2, therefore the light ray refracts tangent to the separating surface. If the ratio between the speed of light in medium 1 and that in medium 1 equals 10.73, then the critical angle between the two media equals 11.

(a) 39.65°

(b) 41.8°

c 46.89°

d 49.72°

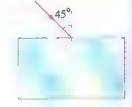

The dispersive power of a thin prism depends on ......

- the angle of incidence of the beam on the prism
- the intensity of the incident light on the prism
- c the apex angle of the prism
- d the refractive index of the prism

\* The opposite figure shows a light ray that falls from air on a transparent glass plate at angle of 45°, therefore the emergence angle of the light ray from the glass plate, if the refractive index of its material is 1.52 equals

(a) 28°

b) 45°

(c) 49°

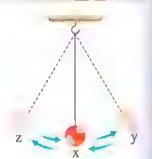

(d) 53°

The opposite figure shows the motion of a simple pendulum of periodic time T, so which of the following statements is wrong?

- b The speed of the load at z = zero
- The amplitude = The distance between z and y
- The time taken by the load to cover the distance  $xy = \frac{T}{4}$

- - \* A light ray falls on one of the faces of equilateral triangular prism of refractive index 1.5 with an angle 60° where the prism makes an angle 60° with a plane mirror as in the opposite figure, therefore the angle of its reflection

(a) 0°

- (b) 21.1° (c) 38.9°

- (d) 68.9°
- A liquid flows steadily in tube x of cross-sectional area 26 cm<sup>2</sup> that is branched into two tubes y and z that have cross-sectional areas of 15 cm<sup>2</sup> and 7 cm<sup>2</sup> respectively. If the speed of the liquid in the tubes x and y are 0.4 m/s and 0.6 m/s respectively, so the speed of liquid flow in tube z equals ......
  - (a) 0.2 m/s
- (b) 0.3 m/s

 $0.5 \, \text{m/s}$ 

0.7 m/s

The opposite figure represents the relation between the first angle of refraction  $(\theta_1)$  and the second angle of incidence (\$\phi\_2\$) in a glass triangular prism, so the apex angle of the prism equals ......

b 45°

c 50°

60°

- In the opposite figure, as the boat gets closer to the shore while keeping its speed constant, the athlete needs to .....
  - (a) row with a less force
- b row with a greater force
- c row with the same force stop rowing
- The opposite figure shows the occurrence of mirage, hence the correct order for the wavelengths of light in the three air layers is .....

$$\lambda_1 > \lambda_2 > \lambda_3$$

$$(b)$$
  $\lambda_3 > \lambda_2 > \lambda_1$ 

$$\bigcirc \lambda_3 > \lambda_1 > \lambda_2$$

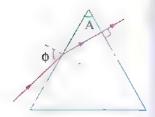

A light ray falls on one of the faces of a triangular prism and emerges normal to the opposite face as in the opposite figure, so the angle of incidence (\$\phi\$) is ......

(b) less than A c) equal to A

(d) equal to (90 - A)

The opposite figure shows a light source that is placed inside a transparent medium, so what happens to ray (3) at the boundary surface between the two media?

It gets refracted, because the angle of incidence is less than the critical angle between the two media

It gets refracted, because the angle of incidence is greater than the critical angle between the two media

It gets totally reflected, because the angle of incidence is less than the critical angle between the two media

It gets totally reflected, because the angle of incidence is greater than the critical angle between the two media

Which of the following is correct when comparing between the refraction and the diffraction of light?

The diffraction happens when light transfers from one medium to another while the refraction happens when light propagates in the same medium The diffraction happens when light propagates in the same medium while the refraction happens when light transfers from one medium to another Both of them happen when light propagates in one medium

Both of them happen when light transfers from one medium to another

\* A light ray falls perpendicularly on one of the faces of a triangular prism of refractive index  $\sqrt{2}$  to emerge tangentially to the opposite face, therefore the angle of minimum deviation of the light ray in the prism equals ..... approximately.

### Choose the correct answer (1 20)

The figure that represents the direction of the vibration of the particles of medium (a) relative to the direction of the propagation of a transverse wave ( is medium is medium ).

- The ratio between the first angle of incidence and the angle of emergence of a light ray, that falls on one of the faces of a triangular prism which is at the minimum deviation position, is ......
  - a greater than 1
  - (b) less than 1
  - © equal to 1
  - d we can't determine the answer without knowing the value of the apex angle of the prism
- - a) 1 mm
- (b) 2 mm
- (c) 3 mm
- (d) 4 mm
- - $\frac{1}{2}$

(b)  $\frac{2}{1}$ 

© 1/4

d 4/1

At inhalation, the air flows through the trachea with a speed of 15 cm/s. If the cross-sectional areas of each of the two branches of the trachea are quarter that of the main trachea and considering the air flow is steady, then the speed of the air flow in each branch is

- (a) 7.5 cm/s
- (b) 15 cm/s
- (c) 30 cm/s
- (c 45 cm/s

- (a) less than 1
- b greater than 1
- © equal to 1
- d can't define the answer

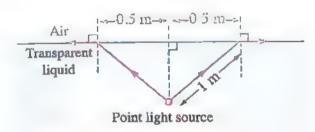

The opposite figure shows light rays that are produced from a point light source placed in a transparent liquid. So, the refractive index of this liquid is ------

(a) 1.5

**b** 1.7

(c) 1.8

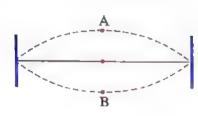

(d) 2

- (b) 50 Hz
- (c) 100 Hz
- d) 200 Hz

A thin prism is submerged in water where it deviates the light rays that fall on it from the water by an angle of 0.9°. If the refractive index of the prism's material is 1.5 and the refractive index of water is 1.33, then the apex angle of the prism is ..... approximately. (c)6°

If the speed of the light rays through a transparent medium is  $2.4 \times 10^8$  m/s, then the critical angle of the medium with air equals ......  $(c = 3 \times 10^8 \text{ m/s})$ 

(1) 39.4°

a) 80

(b) 42.61°

(b) 7°

(c) 48.2°

d 53.13°

In the double-slit experiment, a student used laser rays of wavelength 632.8 nm and he placed the observation screen 1 m away from the double-slit. He finds that the distance between the center of the first bright fringe and the center of the central fringe is 3.2 mm. so the distance between the two slits is ......

a) 19.8 mm

(b) 198 µm

(c) 50.6 mm

(d) 506 µm

The following measuring units are equivalent to each other except ......

(a) kg.m<sup>2</sup>/s<sup>2</sup>

(b) N.s/m<sup>2</sup>

(b) 50

c) 75

The opposite figure represents a hill that separates between a TV transmission station and a house. Although the hill acts as a shield for the station but the house receives the TV station perfectly, so what happened to the TV TV had r waves at the hill? (a) Refraction b) Diffraction (c) Interference d) Reflection When a light ray falls on one of the faces of an equilateral triangular prism in the position of minimum deviation, the second angle of incidence equals ..... (a) 30° (b) 45° (c) 60° Second Answer the following questions (22: 27) A light ray falls on an optical fiber cable that is made of a flexible material of refractive index 1.65. Calculate the least angle of incidence of the light ray that falls on the internal surface of the cable to undergo total internal reflection. A light ray falls on an optical fiber cable that is made of a flexible material of refractive index 1.65. Calculate the least angle of incidence of the light ray that falls on the internal surface of the cable to undergo total internal reflection.

- From your and is the advice that you can give to the drivers to save fuel on roads?
  - Asimple pendulum is displaced from its original position,
    then it is left to swing with a simple harmonic motion,
    at which position, the speed of the pendulum's bob becomes
    maximum?

    B
- From the opposite figure, calculate the value of angles  $\phi_1$  and  $\theta_1$ .

  (Knowing that:  $\sin (90 \theta) = \cos \theta$ )

  The value of angles  $\phi_1$  and  $\phi_1$ .

  Water  $\phi_1 = 1$   $\phi_1 = 1$   $\phi_2 = 1.33$   $\phi_1 = 1$   $\phi_1 = 1$   $\phi_2 = 1.33$   $\phi_1 = 1$   $\phi_1 = 1$   $\phi_2 = 1.33$
- The opposite figure shows the path of a light ray that falls on one of the faces of a triangular prism, calculate:

  (a) The refractive index of the prism's material.

  (b) The angle of deviation of the light ray.

#### Choose the correct answer

- (d) 0.36°
- 2 a 1 2
- 3 (c) 0.1, 0.5
- $(0.04 \text{ m}^2)$

(d) 4 v

(d)√3

0 C 4

- (a) greater than 1
- 9 (d) 1 m/s, 2 m/s
- 10 (a) 10 Hz
- (d) 633 nm
- (b) point b
- (B) (d) Cylinder 4
- 0 (b) (1)
- (b) (d) mechanical waves
- (a) greater than 1
- (d) increases in area
- 18 (a) 1
- $\bigcirc 0 \bigcirc 1.35$

20 (c) 0.2

## Second Answer the following questions

$$\alpha_0 = A\left(\frac{n_2}{n_1} - 1\right) \qquad \therefore \alpha_0 = 8\left(\frac{1.5}{\frac{4}{3}} - 1\right)$$

$$\alpha_0 = 1^\circ$$

- Because of the viscosity of air, the air layers which is closer to the ground move slower than the layers which are at high distances from the ground.
- 24 From water to the plastic plate:
  - 1.33 sin 35°
  - $= 1.5 \sin \theta$
  - ∴  $\theta_1 = 30.6^{\circ}$  From plastic plate

    30.6°

    Water

    30.6° Plastic plate
  - to air:
    - $1.5 \sin 30.6 = \sin \theta_{3}$  $\theta_2 = 49.7^{\circ}$

#### Another Solution:

1.33 sin 35° = sin 
$$\theta_2$$
  
 $\theta_2 = 49.7$ °

 $25 1.5 \sin 30 = \sin \theta$ ∴ θ = 48.6°

26 - Wave A:  $v_A = \frac{X_A}{t_A} = \frac{60 \times 10^{-2}}{0.3 \times 10^{-3}} = 2000 \text{ m/s}$ 

$$v_B = \frac{X_B}{t_B} = \frac{60 \times 10^{-2}}{0.3 \times 10^{-3}} = 2000 \text{ m/s}$$

- (a) :  $(\sin \phi_c)_1 = \frac{n_{\text{air}}}{n_{\text{water}}}$  :  $\sin 48 = \frac{1}{n_{\text{water}}}$ 

  - $\therefore$  n<sub>water</sub> = 1.34
  - $\therefore (\sin \phi_c)_2 = \frac{n}{n}$   $\therefore \sin 44 = \frac{1}{n}$
  - $n_{oil} = 1.44$

$$rac{1.44}{m_o} = \frac{n_{oil}}{n_{water}} = \frac{1.44}{1.34} = 1.07$$

- **(b)** :  $\sin \phi_c = \frac{n_{\text{water}}}{n_{\text{cr}}}$  :  $\sin \phi_c = \frac{1.34}{1.44}$ 

  - $\phi_0 = 68.52^{\circ}$

### Answer of General Exam

## Girst Choose the correct answer

- (b) 2.24 m/s
- 2 (a) 1

(c) 1.7

(d)

**5** (b) 7.5

- (c) 0
- (d) 68.4 m
- $8 \ 6 \ \frac{5}{3}$

- 9 (d) 1.5 d
- (a) 1.33
- (d) 37.8°
- (12 (b) refracts toward the normal
- (B)(d) 225

(C) 6 s

(b) (d) 99.3°

- 16 (b) 45°
- (b) always dark
- 18 b the source frequency
- (19 (a) greater than 1
- (d) the refraction coefficient of the prism
- (d) totally reflects

- To decrease the heat produced due to friction, to protect the machine parts from corrosion and to increase their efficiency.
- $\triangle y \simeq \Delta y \simeq \frac{\lambda R}{d}$
- $d = \frac{\lambda R}{\Delta v}$
- $\therefore d = \frac{575 \times 10^{-9} \times 2.75}{2.75 \times 10^{-3}} = 575 \ \mu m = 5.75 \ mm$
- Momentum = Mass × Velocity
  - : The viscosity of water is greater than that of air.
  - : The velocity of the body decreases more quickly when it moves in water than in air.

- : momentum « velocity
- .. The momentum of the body also decreases in water more quickly than in air.
- 25 (a)  $\sin 45 = \sqrt{2} \sin \theta$ ,  $\sqrt{2} \sin 30 = \sin \theta_2 \therefore \theta_2 = 45^\circ$ 
  - (b)  $\therefore \alpha = \phi_1 + \theta_2 A \quad \therefore \alpha = 45 + 45 60 = 30^\circ$
- 26 (a)  $A = \frac{60-10}{2} = 25$  cm (b)  $d = 2 \times 4 \times 25 = 200 \text{ cm}$
- The light will emerge to the water because its angle of incidence is less than the critical angle between water and glass, where:

 $\sin \phi_c = \frac{n_w}{n_c} \qquad \qquad \sin \phi_c = \frac{1.33}{1.58}$ 

 $\therefore \phi_0 = 57.3^\circ$ 

#### Answer of General Exam

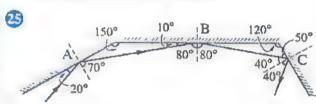

#### First Choose the correct answer

- 1 a R
- $2 \cdot a \cdot \frac{5}{6}$
- $\bigcirc$  (d) 2.8 N.s/m<sup>2</sup>
- (d) 844.8 cm
- (d) 80°, 1.35
- (c) 46.89°
- (a) decreases
- (8) (a) increases
- (c) The amplitude = The distance between z and y
- (b) 5, 0.2
- (1) (a) 0.2 m/s
- (12 (c) 50°
- (B) (b) row with a greater force
- (A) (b) 1

- (15 (a) greater than A
- (b) It gets reflected because the angle of incidence is greater than the critical angle between the two media
- (d) remains constant
- (18 (b) The diffraction happens when light propagates in the same medium and the refraction happens when light transfers from one medium to another
- (c) frequency
- 20 (d) 471 kg
- (d) all the previous

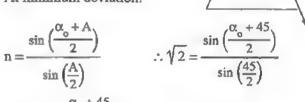

### Second Answer the following questions

- $\mathfrak{D} : \mathfrak{n}_1 \sin \phi_1 = \mathfrak{n}_2 \sin \theta_1$ 
  - $\cdot \cdot \cdot \phi_2 = \theta_1$
  - $\therefore$  n<sub>2</sub> sin  $\phi_2 = n_1 \sin \theta_2$
  - $\therefore \theta_2 = \phi_1 = 45^{\circ}$
- The wavelength of red light is greater than that of blue light and as  $\Delta y \propto \lambda$ 
  - .. The interference fringes will be more separated and noticeable.
- 24 The vibrational motion is considered a periodic motion because the body vibrates and repeats its motion in regular time intervals, but not every periodic motion is considered a vibrational motion as the motion of the Moon around Earth where it repeats itself in regular time intervals but it is not considered a vibrational motion.

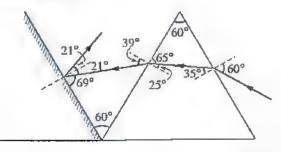

- - :. A = 45°

At minimum deviation:

- $\therefore 32.8^{\circ} = \frac{\alpha_0 + 45}{2}$  $\Rightarrow \phi_1 = \theta_2 = \frac{\alpha_0 + A}{2}$   $\Rightarrow \phi_1 = \frac{20.5 + 45}{2} = 32.8^\circ$
- Angle of reflection from the surface of the mirror  $= 21^{\circ}$

#### First Choose the correct answer

- (1) (b) 50°
- 2 b 0.625 N
- 3 © 59.36°
- 4 a  $v_A < v_B$
- 650 nm
- $\cdot 6 \odot T_1 > T_2 > T_3$
- (7) © remains constant
- 8 b 45°
- $\bigcirc$  **b** 6.74 × 10<sup>-3</sup> m/s
- **(1)** (b) 1.5
- 1 a 0.11 m<sup>2</sup>
- (D(d))
- (B) © 1.62
- (1) © yellow
- (Ba) 1.5
- 16 © Constant, Constant
- (b) gets refracted away from the normal line
- (B) (b) 40°
- $(b) \phi = \theta = 0^{\circ}$
- 20 C 60°
- 21 © increases, decreases

## Second Answer the following questions

 $\sin \phi = n \sin (90 - \phi)$ 

 $\sin \phi = 1.55 \cos \phi$ 

 $\tan \phi = 1.55$ 

 $\phi = 57.17^{\circ}$ 

- 23 : Amplitude = 10-7=3 cm
  - ∴ The distance covered in complete vibration
    = 3 × 4 = 12 cm
  - ∴ The distance covered during five complete vibrations = 12 × 5 = 60 cm
- Because the angle of minimum deviation is defined from:

$$n = \frac{\sin\left(\frac{\alpha_o + A}{2}\right)}{\sin\left(\frac{A}{2}\right)}$$

and A is constant for the same prism but the refractive index (n) changes by changing the wavelength of the used light, so the angle of minimum deviation changes with the wavelength.

**25** : 
$$\tan \phi_c = \frac{12}{9} = \frac{4}{3}$$

∴ 
$$\phi_0 = 53^\circ$$

$$\therefore n = \frac{1}{\sin \phi_c}$$

$$=\frac{1}{\sin 53} = 1.25$$

26 (a) 
$$v = \frac{d}{1} = \frac{136}{0.4} = 340 \text{ m/s}$$

(b) 
$$d = \frac{1}{2} \lambda = \frac{1}{2} v T = \frac{1}{2} (340 \times 4 \times 10^{-3}) = 0.68 m$$

$$\Delta y = \frac{\lambda R}{d}$$

$$6 \times 10^{-3} = \frac{\lambda \times 100 \times 10^{-2}}{8 \times 10^{-5}}$$

$$\lambda = 4.8 \times 10^{-7} \text{ m}$$

$$\therefore v = \frac{c}{\lambda} = \frac{3 \times 10^8}{4.8 \times 10^{-7}} = 6.25 \times 10^{14} \text{ Hz}$$

### **Answer of General Exam**

12 cm

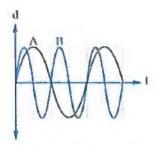

### First Choose the correct answer

- **1 b**
- 3 (d) 4 mm
- 5 © 30 cm/s
- 7 d 2
- 9 b 7°
- **(1)** (b) 198 µm
- 2 © equal to 1
- 4 d 4/1
- 6 b greater than 1
- 8 © 100 Hz
- (I) (d) 53.13°
- $\bigcirc$  (a) kg.m<sup>2</sup>/s<sup>2</sup>
- (3 a) water increases by decreasing the crosssectional area of the nozzle
- 14 d zero, maximum
- (5) c emerges normal to the opposite face
- $\bigcirc \boxed{4}$
- $\mathbf{v}$  (a)  $\frac{1}{2}$
- $\mathbb{B} \odot \frac{5}{1}$
- (a) longitudinal
- (2) (c) when they encounters a sharp edge

## Second Answer the following questions

Because when the outside is dark, the amount of light passing from the outside is very small, so the person can see his image as a result of the reflection of the small amount of light reflected by the glass of the room's window and when there is light outside, the amount of light passing from outside is larger than the amount of the reflected light, so it is difficult for the person to see his image.

2

- Because the angle of deviation depends on the refractive index of the prism for the light color and it is inversely proportional to the wavelength of the light, so as the wavelength of violet light is less than the wavelength of red light, hence the angle of deviation of violet light is larger than that of red light.
- $\sin \phi_c = \frac{n_2}{n_1} = \frac{\lambda_1}{\lambda_2} \qquad \therefore \sin \phi_c = \frac{\lambda_A}{\lambda_D} = \frac{450}{600}$

$$\therefore \sin \phi_c = \frac{\lambda_A}{\lambda_B} = \frac{450}{600}$$

∴ \$ = 48.6°

, and it is located in medium A

 $Q_{0} : Q_{0} = Av$ 

$$\therefore \frac{V_{ol}}{t} = \pi r^2 v$$

 $\therefore \frac{m/\rho}{r} = \pi r^2 v$ 

$$\therefore \frac{100/900}{25 \times 60} = \pi r^2 (0.2)$$

27

#### **Answer of General Exam**

6

#### First Choose the correct answer

- (b) greater than the critical angle between the prism and the liquid
- (2) (d) 45°, √2
- (3) (c) changes, remains constant
- (1) (d) 1/1
- (5) (a) 37°
- (c) equal to 1
- (b) sixth bright fringe

- (b) 4.25 m
- (d) 1.61
- (b) 0.77 kg/s
- (c) 23.8°, 45°
- (b) 50°
- (B) (b) the temperature of the fluid
- (d) (4)
- (a) x to z
- (a) wavelength decreases to its half
- (f) (d) the wavelength of light in the first medium is smaller than the wavelength of light in the second medium
- 18 (d) 51°
- (1) (a) greater than 1
- (c) interference
- (c) the speed of the liquid at A is less than the speed of the liquid at B

- $\triangle y = \frac{4 \times 10^{-3}}{2} = 2 \times 10^{-3}$  m
  - $\therefore \Delta y = \frac{\lambda R}{J}$

$$\therefore \lambda = \frac{\Delta y \, d}{R} = \frac{2 \times 10^{-3} \times 7 \times 10^{-4}}{200 \times 10^{-2}} = 7 \times 10^{-7} \, \text{m}$$

- Δ3 The first angle of incidence (φ,) = The angle of emergence  $(\theta_2) = \phi_0$ 
  - The first angle of refraction  $(\theta_1)$  = The second angle of incidence  $(\phi_2) = \theta_0$
- The speed of water currents near the riverside is less than their speed in the middle of the river, so the aquatic plants could be seen at the slower currents region.
- (a)  $v = \frac{N}{t} = \frac{2048}{8} = 256 \text{ Hz}$ 
  - **(b)**  $T = \frac{1}{10} = 3.9 \times 10^{-3} \text{ s}$
- The optically rarer material (which has less refractive index) is used to make the external layer of the optical fiber, so it can reflect the light that may escape from the inner core. So, the double layer fiber decreases the loss of light energy.
- ②  $\phi_1 = \theta_1 = 0^{\circ}$  ,  $A = \phi_2 = 45^{\circ}$ ∴ 1.7  $\sin \phi_2 = \frac{4}{3} \sin \theta_2$  ∴ 1.7  $\sin 45 = \frac{4}{3} \sin \theta_2$ 
  - $\theta_{2} = 64.36^{\circ}$
  - $\Rightarrow \alpha = \phi_1 + \theta_2 A$
  - $\alpha = 0 + 64.36 45$   $\alpha = 19.36^{\circ}$

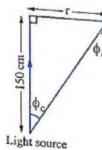

### First Choose the correct answer

- (b) 10, 2
- (b) 1000 s
- 3 (a) 1.41
- (c) 0.03
- (b) 60°
- 6 (b) 5 mm
- (b) 2560 vibrations
- ® (b) 21.73°
- (b) 40.75°
- (I) (C) 1.75 N.s/m<sup>2</sup>
- (c) 1.8 m/s
- (C) A, C
- (B) decrease
- (a) 30°
- (B) (a) 6°
- (d) 60 cm
- (a) the absolute refractive index of glass is greater than the absolute refractive index of the other medium
- 18 b 1/2
- (b) less than one
- (b) radio waves
- (a)  $n_2 < n_1$

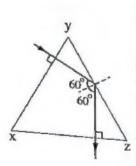

# Second Answer the following questions

- Because as the temperature increases, the viscosity of the fluids decreases, so honey flows faster in summer.

- $\therefore \Delta y = \frac{\lambda R}{d} \qquad \therefore \lambda = \frac{\Delta y \, d}{R}$   $\therefore \lambda = \frac{4.5 \times 10^{-3} \times 0.1 \times 10^{-3}}{100 \times 10^{-2}} = 4.5 \times 10^{-7} \, \text{m}$
- 2 :  $\sin \phi_c = \frac{1}{n}$ 
  - $\therefore \sin \phi_c = \frac{1}{1.33}$
  - $\therefore \phi_c = 48.75^\circ$
  - $\because \tan \phi_c = \frac{r}{150}$
  - :  $tan (48.75) = \frac{r}{150}$
  - $\therefore$  r = 171 cm

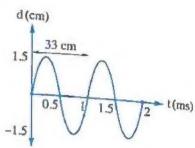

- $25 \approx \sin \phi_c = \frac{1}{n}$ 
  - $\sin \phi_c = \frac{1}{1.5}$
  - $\therefore \phi_c = 41.8^\circ$
  - $: \phi_2 > \phi_c$
  - .. The ray will totally reflect inside the prism.

(a) Longitudinal wave.

(b)

- $\theta_a > \theta_c > \theta_b$

## Answer of General Exam

8

# First Choose the correct answer

- 1 (a) 30°
- 2 (d) X and Z
- (d) red
- (d) total internal reflection
- (S) (c) equal to one
- (d) 24.6°
- 7 (c) 8°
- 8 (c) 48.59°
- (1) doesn't change
- (II) (II) transverse, longitudinal
- (b) 12.06°
- 10 d) 4
- **®** ⓑ 25.8°
- 10 (c) 5/3 Hz
- (Sa) material A
- (16) (a) greater than one
- (C)
- $\bigcirc$  a  $\bigcirc$  hour
- (1) (a)  $2 \times 10^{-3}$  s (1) (d) 4 λ,
- 20 (d) 90°

- 2 :  $\sin \phi_c = \frac{1}{n}$
- $\therefore \sin 42 = \frac{1}{n}$
- n = 1.49
- ∵ sin φ = n sin 25°
- $\therefore \sin \phi = 1.49 \times \sin 25$
- ∴  $\phi = 39.17^{\circ}$
- $rac{\sigma}{\Delta} : D = \frac{1}{\Delta}$

- $\therefore \frac{\mathbf{v}_1}{\lambda_1} = \frac{\mathbf{v}_2}{\lambda_2} \qquad \qquad \therefore \frac{\mathbf{v}_1}{\lambda_1} = \frac{\mathbf{v}_2}{\lambda_1 + 10}$
- $\therefore v_1(\lambda_1 + 10) = v_2 \lambda_1 \qquad \therefore \frac{v_1}{v_2} = \frac{\lambda_1}{\lambda_1 + 10}$
- $\therefore \frac{2}{3} = \frac{\lambda_1}{\lambda_1 + 10}$
- $\therefore \lambda_1 = 20 \text{ cm} \quad , \quad \lambda_2 = 30 \text{ cm}$

$$\therefore \, \phi_2 = 14^{\circ}$$

$$\phi_2 = \theta_1 = 14^\circ$$

$$\therefore \phi_2 = \theta_1 = 14^{\circ} \qquad \therefore \sin \phi_1 = n_2 \sin \theta_1$$

$$\therefore \sin \phi_1 = 1.6 \sin 14 \qquad \therefore \phi_1 = 22.8^{\circ}$$

$$\phi_1 = 22.8^\circ$$

$$(\Delta y)_A = \frac{\lambda R_A}{d_A}$$

$$(\Delta y)_A = \frac{\lambda R_A}{d} \qquad \therefore (\Delta y)_A = \frac{\lambda (0.6)}{0.15 \times 10^{-3}}$$

$$\therefore (\Delta y)_{\Lambda} = 4000 \lambda$$

$$:: (\Delta y)_{B} = \frac{\lambda R_{B}}{d_{B}}$$

$$\therefore (\Delta y)_{B} = \frac{\lambda R_{B}}{d_{-}} \qquad \therefore (\Delta y)_{B} = \frac{\lambda (0.8)}{0.175 \times 10^{-3}}$$

$$\therefore (\Delta y)_{R} = 4571 \lambda$$

$$\therefore (\Delta y)_{\mathbb{C}} = \frac{\lambda R_{\mathbb{C}}}{d_{\mathbb{C}}}$$

$$\therefore (\Delta y)_{\rm C} = \frac{\lambda (0.8)}{0.15 \times 10^{-3}}$$

$$(\Delta y)_{C} = 5333 \lambda$$

$$\therefore (\Delta y)_A < (\Delta y)_B < (\Delta y)_C$$

#### (a) $\theta = 90^{\circ} - 22^{\circ} = 68^{\circ}$

**(b)** : 
$$n = \frac{1}{\sin \phi_c}$$
 :  $n = \frac{1}{\sin 59}$  :  $n = 1.17$ 

$$\therefore n = \frac{1}{\sin 59}$$

$$\therefore$$
 n = 1.17

To increase the flow speed of water at the nozzle of the hose where the flow speed of water is inversely proportional to the cross-sectional area based on the continuity equation, so the water rushing out of the hose can reach far distances. If the hoses are of wider nozzles, the water speed at the nozzle will decrease.

#### Answer of General Exam

#### First Choose the correct answer

(b)

- (2) (b)  $\lambda_{violet} < \lambda_{red}$
- (d) 336.6 m/s
- (c) 45°
- (b) 1.77 m/s
- (6) 71.33° and it is located in the container medium
- **7** (b)

- (a) greater than 1
- (a) 3 cm
- (C) 16
- (1) (b) Viscosity coefficient (12) (c) 60°
- (13 (d) the density of the liquid
- (a) 1/1
- a 10,0 (b)
- ((a) 1.11
- (a) 35.26°

- 1B (d) y
- $(2.5 \times 10^8 \text{ m/s})$
- (a) fringes become more distant from each other
- (c) 3

#### Second Answer the following questions

- Because the range of wavelengths of visible light extends from 400 nm to 700 nm which are very small wavelengths so that light diffraction doesn't appear because visible light needs very small aperture sizes for the appearance of light diffraction patterns.
- As temperature decreases, the viscosity of the liquid increases, its resistance to the motion of a solid object inside it increases where the frictional forces between the liquid and the object increases.
- The two waves propagate in the same medium.
  - $\therefore v_1 = v_2$
- $\therefore \frac{\lambda_1}{\lambda} = \frac{1}{T}$
- $\therefore \frac{\lambda_1}{\lambda} = \frac{\frac{1}{2} T_2}{T} \qquad \therefore \frac{\lambda_1}{\lambda} = \frac{1}{2}$
- The light ray deviates by an angle of 28°
  - $\theta_0 = \alpha + A = 28^{\circ} + 35^{\circ} = 63^{\circ}$
  - $\therefore$  n sin  $\phi_2 = \sin \theta_2$

$$\therefore n = \frac{\sin \theta_2}{\sin \phi_2} = \frac{\sin 63}{\sin 35} = 1.55$$

(a)  $(\alpha_s) = A(n-1) = 8(1.5-1) = 4^\circ$ 

$$(\alpha_o)_b = A(n_b - 1) = 8(1.55 - 1) = 4.4^\circ$$

$$\therefore (\alpha_{o})_{y} = \frac{(\alpha_{o})_{b} + (\alpha_{o})_{r}}{2} = \frac{4 + 4.4}{2} = 4.2^{\circ}$$

**(b)** 
$$(\alpha_o)_b - (\alpha_o)_r = 4.4 - 4 = 0.4^\circ$$

- (a)  $_{w}n_{o} = \frac{n_{o}}{n_{w}} = \frac{1.8}{\frac{4}{3}} = 1.35$ 
  - (b) :  $n_w \sin \phi_1 = n_o \sin \theta_1$ 
    - $\therefore \frac{4}{3} \sin 60 = 1.8 \sin \theta_1$
- $\theta_1 = 39.9^{\circ}$  $\sin \phi_c = \frac{1}{1.9}$
- $\theta_1 = \phi_2 = 39.9^{\circ}$
- $\therefore \phi_{a} = 33.75^{\circ}$
- .. The ray will not refract into air.

10

## First Choose the correct answer

- 1 b 4 N
- 2 (a) 0.003 m
- **3 d** 1.66
- (d) 1.75
- $\bigcirc$  (d)  $3 \times 10^{-3}$ , 12
- **6 b** 100, 30
- (a) remains constant
  - (8) (d), 1.2 mm
- (1) (d) 75°, 60°
- (10 (b) 48.59° in medium Y
- (C) 1.72
- (1) (c) the distance between the two slits increases
- (B) (a) emerge tangent to this face
- (a) 0.2 cm/s
- (15 (a) greater than 1
- 16 d Mechanical energy
- (b) the first angle of incidence
- (18 (a) the wavelength increases
- (D) (2) 25
- 20 (b) Diffraction
- 21 (a) 30

- $2 \cdot \lambda = \frac{v}{v}$
- $: d = \lambda N$
- $d = \frac{v}{v} N = \frac{340}{102} \times 12 = 40 \text{ m}$
- $\sin \phi_{c} = \frac{1}{n}$
- $\therefore \sin \phi_c = \frac{1}{1.65}$
- $\therefore \phi_c = 37.3^{\circ}$

- In medium and uniform speeds air resistance resulting from air viscosity is directly proportional to the speed of the moving body and when the speed exceeds a certain limit, the air resistance becomes directly proportional to the square of the speed and not the speed itself leading to a noticeable increase in fuel consumption, so the driver has to consider not exceeding such limit (80 90 km/h).
- **4** At position O
- $\Theta_1 = 90 \phi_2$ 
  - $\forall \phi_1 = \phi_2$
  - $\therefore \theta_1 = 90 \phi_1$
  - $\because \sin \phi_1 = 1.33 \sin \theta_1$
  - $\therefore \sin \phi_1 = 1.33 \sin (90 \phi_1)$
  - $\therefore \sin \phi_1 = 1.33 \cos \phi_1$
  - $\therefore \ tan \ \varphi_1 = 1.33$
  - $\therefore \phi_1 = 53^{\circ}$
  - $\theta_1 = 90^{\circ} 53^{\circ} = 37^{\circ}$
- ② (a) ::  $n \sin 30 = \sin 49$ 
  - n = 1.5
  - **(b)** :  $\sin \phi_1 = 1.5 \sin 35$ 
    - ∴  $\phi_1 = 59.36^{\circ}$
    - $\therefore \alpha = \phi_1 + \theta_2 A$
    - $\alpha = 59.36 + 49 65 = 43.36^{\circ}$
